INDEX TO VOLUME CLXXII.

AUTHORS.

- Abrahams, H.** Suggestions in the employment of labor, 552.
- Allen, F. M.** The treatment of diabetes, 241.
- Arkin, L.** A case of autotransplantation of bone for nasal deformity due to syphilis, 672.
- Armstrong, D. B.** Occupational disease and the public health, 51.
- Austin, A. E.** Progress in biochemistry, 377. The clinical use of the water meal in determining the secretory and motile powers of the stomach, 857.
- Balch, F. G.** A report on some cases of perineal prostaticectomy, 507.
- Bancroft, C. P.** Some perils confronting state care of the insane, 247.
- Bartlett, P. C.** Progress in tuberculosis, 138.
- Bates, Everett A.** Annual discourse—some perplexities in modern medicine, 843.
- Beckley, C. C.** Border-line cases of mental defect with special reference to hysterical symptoms, 510.
- Berry, G.** Labyrinthitis following operation for atresia, 700.
- Bieberbach, W. D.** Venereal disease and prostitution, 201.
- Blaisdell, J. H.** The menace of syphilis to the clean-living public, 476.
- Boardman, M. T.** The patriotic and humane service of the Red Cross nurse, 503.
- Bowen, J. T.** Report on dermatology, 709.
- Bradford, E. H., and Sauter, R.** On the fixation of fractured bones in infants and young children, 508.
- Briekley, W. J.** The relation of alcohol to accidents, 744.
- Bryant, J.** The carnivorous and herbivorous types of man, 321.
- Bucholz, H., et al.** Seventh report of progress in orthopedic surgery, 59, 97.
- Bufford, J. H., and Lane, C. G.** Cutaneous tuberculosis. Report of a case of folliculitis and erythema induratum, 825.
- Cabot, H.** Some observation upon diverticulum of the bladder, 300; observations upon ten cases of diverticulum of the bladder, 365.
- Cabot, R. C.** James Gregory Mumford, M.D., 470.
- Canavan, M. M.** A study of normal-looking brains in psychopathic subjects, 124.
- Chadwick, H. D.** Treatment of tuberculous cervical adenitis, 5.
- Chase, H. M., and Tenney, B.** Mortality after prostatectomy based on a study of 229 fatal results, 437.
- Cheever, D. W.** The changed position of the profession of medicine, 473.
- Christian, H. A.** The starvation method versus gradual carbohydrate reduction as a time saver in the treatment of diabetes, 929.
- Clap, E. W.** Progress in ophthalmology, 21.
- Clark, L. P.** A study of the epilepsy of Dostojewsky, 46.
- Cole, L. G., and George, A. W.** The Roentgen diagnosis of gall-stones by improved methods, 326.
- Cory, T. K.** Suggestions in the employment of labor, 551.
- Cotton, F. J.** An undescribed ulnar nerve trouble due to tension from scar, and its cure, 480.
- Coues, W. P.** Thackeray's physicians, 302; The diagnosis and treatment of some rare fractures, 705.
- Courtney, J. W.** Some nervous affections in which massage deserves more frequent use, 483.
- Crane, B. T.** Remarks on the diagnosis and treatment of pulmonary tuberculosis, 433.
- Crosbie, A. H.** The field for local anesthesia and of spinal anesthesia in genito-urinary surgery, 260.
- Crosbie, A. H., and Riley, A.** Epididymotomy for epididymitis, as an out-patient procedure, 664.
- Cutter, E. G.** Water drinking. When shall we drink water? May we take it with meals? 925.
- Dana, H. W.** The treatment of pneumonia in children. Report of 104 consecutive cases, 58.
- Danforth, M. S., et al.** Seventh report of progress in orthopedic surgery, 59, 97; Eighth report of progress in orthopedic surgery, 443, 486.
- Davis, L.** A study of 260 cases of acute appendicitis at the Massachusetts General Hospital, 737; Two cases of rupture of intestine, 163.
- DeNormandie, R. L., and Swift, J. B.** Report on obstetrics, 590.
- Derby, R.** The care and treatment of the wounded in the European war, 693.
- Dickson, H. L.** Hospital efficiency from the standpoint of a hospital surgeon, 775.
- Downing, A. F.** Syphilis and lung diseases, 898.
- Drinker, C. K.** John Halle: anatomiste, chirurgien, modernist, 575.
- Duckering, F. W.** Plastic surgery in proclittia with report of twenty-five cases, 292.
- Dunn, C. H.** Some studies in fat indigestion, 167; Thomas Morgan Rotch, M.D., 82.
- Emmons, A. H.** Care of prospective mothers, 618.
- Eustis, R. S.** The differentiation of human and cow's milk by color tests, 92.
- Floyd, C.** Tuberculosis in its relation to the handling of food, 549.
- George, A. W., and Cole, L. G.** The Roentgen diagnosis of gall-stones by improved methods, 326.
- Getchell, A. C.** Tuberculosis of the throat, 782.
- Gilbreth, F. H.** Hospital efficiency from the standpoint of the efficiency expert, 774.
- Godda, L. A. O.** Enchondroma. A review of the literature of the subject with report of three cases operated upon by the author, 402.
- Goldschalt, J. E.** An anatomic and mechanistic conception of disease, 881.
- Goldwater, S. S.** Dispensaries: A growing factor in curative and preventive medicine, 613.
- Goodale, J. L.** The parenteral administration of horse serum in cases of horse asthma, 751.
- Green, R. M.** Corsets, ptosis and sacro-iliac strain, 587.
- Gregg, D.** Somatic characteristics of general paretics, 519.
- Hammond, P.** Parotid fistula following mastoid operation, 25.
- Hardwick, R. S.** Program and directions for the mental examination of asocial, psychopathic and doubtful subjects, 817, 861, 906, 935.
- Harmer, T. W.** A study of the efficiency of mixed toxins (Coley) in inoperable sarcoma. A critical analysis of 134 microscopically-proven cases, 331, 373, 411, 410.
- Hatch, F. F.** Progressive neuro-muscular atrophy (peroneal type of Charcot, Marie and Tooth): with report of three cases in a family without heredity, 393.
- Hawes, J. H.** Treatment of tuberculous cervical adenitis, 6; "Do's" and "don'ts" in the diagnosis of early pulmonary tuberculosis in adults and children, 731; The responsibility of the general practitioner for the care and supervision of the discharged sanatorium patient, 779.
- Hawes, J. B., and Bartlett, P. C.** Progress in tuberculosis, 138.
- Hewes, H. F.** A study of the stomach, 286, 339, 370, 406.
- Hill, L. W., and Sherrick, J. L.** Report on the Allen treatment of diabetes, 696.
- Honell, J. A.** A study of leprosy; with especial reference to the pulse and temperature, 580, 629, 668.
- Howard, A. A.** Acidosis in children, 747.
- Hubbard, J. C.** A suggestion in the treatment of hemorrhagic disease of the new-born, 865.
- Hunner, G. L.** A rare type of bladder ulcer in women; report of cases, 660.
- Hutchins, H. T.** A few notes on the treatment of anteposed uteri, 18.
- Jackson, J. M., and Smith, W. D.** Lymphatic leukaemia in acute infection, after removal of the spleen, 136.
- Kendall, A. I.** The relation of bacteria to the etiology of summer diarrhea in young children, 851.
- Klimpton, A. R.** Gangrenous epiploic appendix, report of a case, 752.
- Ladd, W. E.** Modification of technic for hare-lip operation, 54.
- Labey, F. H.** A water-tight ureteral catheter tip, 303.
- Lane, C. G., and Bufford, J. H.** Cutaneous tuberculosis, report of a case of folliculitis and erythema induratum, 825.

- Larrabee, R. C.** A localized subacute form of broncho-pneumonia, 257.
- Linenthal, H.** A case of human rabies, 221; Dangers in handling food by persons afflicted with communicable diseases, 547.
- Lovett, R. W.** Percival Pott, his times and his work, 507.
- Low, H. C., et al.** Seventh report of progress in orthopedic surgery, 59, 97; Eighth report of progress in orthopedic surgery, 448, 486.
- Lowell, H.** Partial tenotomies by the Todd-Harmon method, 56.
- Lyman, D. R.** The tuberculosis work in Connecticut, its development in the last decade, and its future needs, 657.
- Marshall, H. W.** Late results of surgical treatments for flexed scapulae, with a discussion of the subject, 812.
- McLaughlin, A. J.** Dangers in handling food by persons afflicted with communicable diseases, 545; How the practising physician may aid the department of health, 769.
- Monks, G. H.** Experimental use of magnetism for locating needles in the tissues, a preliminary report, 285.
- Morse, J. L., and Talbot, F. B.** The bacteriology of the gastro-intestinal canal in infancy, a summary, 171.
- Osgood, R. B., et al.** Seventh report of progress in orthopedic surgery, 59, 97; Eighth report of progress in orthopedic surgery, 448, 486.
- Otto, E. O.** Communicable diseases and their relation to the handling of food; Introductory remarks, 544.
- Palmer, G. T.** Tuberculous infection as a disease entity, 904.
- Parker, W. S.** Urinary acidity and beta-oxybutyric acid determinations in recurrent vomiting, 164.
- Porter, W. T.** Charles Sedgwick Minot, M.D., 467.
- Post, A.** Dangers from syphilis, 550.
- Preble, W. E.** Obesity and malnutrition, 740.
- Prenn, J.** Sub-mucous resection as a means of obliterating superficial blood-vessels, 138.
- Reed, A. C.** Rabies in China, 901.
- Reid, W. D.** Myxedema simulating nephritis, 674.
- Richards, G. L.** Relation of the tonsils, adenoids and other throat conditions to tuberculous cervical adenitis, 1.
- Riley, A., and Crosbie, A. H.** Epididymotomy for epididymitis as an out-patient procedure, 664.
- Risley, E. H.** Skeletal cancer, 584; The pre-operative diagnosis of tubercular mesenteric and retroperitoneal glands, 253; Diabetes and surgery, 90.
- Robbins, W. B.** Charles Pickering Putnam, M.D., 84.
- Robey, W. H.** Renal infections, 217.
- Rogers, O. F.** A study of children with positive skin tuberculin reactions, 161.
- Seudder, C. L.** The significance of x-ray examination following operation for congenital pyloric tumor, 166.
- Sherrick, J. L., and Hill, L. W.** Report of the Allen treatment of diabetes, 696.
- Smith, O. C.** Differential diagnosis and indications for treatment of tumors of the neck, 208.
- Smith, T.** Scholarship in medicine, 121.
- Smith, W. D., and Jackson, J. M.** Lymphatic leukaemia in acute infection, after removal of the spleen, 136.
- Smithwick, M. P.** Posterior gastro-enterostomy by exact measure, 860.
- Sobotky, I.** The alcoholic injection of the internal branch of the superior laryngeal nerve, 96.
- Solomon, H. C., and Wells, E. S.** Varieties of the gold sol test (Lange) in several loci of the cerebro-spinal fluid system; a study of twenty-eight autopsied cases, 625; On the value of the gold sol test (Lange) in cerebro-spinal fluid obtained post-mortem, 398.
- Southard, E. E., and Canavan, M. M.** A study of normal-looking brains in psychopathic subjects, 124.
- Soutter, R., and Bradford, E. H.** On the fixation of fractured bones in infants and young children, 508.
- Soutter, R., et al.** Seventh report of progress in orthopedic surgery, 59, 97; Eighth report of progress in orthopedic surgery, 448, 486.
- Stearns, A. W.** Note on the recent extension of out-patient work in Massachusetts hospitals for the insane, 553.
- Stedman, H. R.** Report of progress in mental diseases, part I, 223; part II, 262.
- Storer, M.** On ovarian transplantation: with report of a case of implantation into the uterus with resulting pregnancy, 41.
- Swift, H. M.** Compensatory exercises as an aid in the treatment of locomotor ataxia, 85.
- Swift, J. B., and DeNormandie, R. L.** Report on obstetrics, 590.
- Talbot, F. B., and Morse, J. L.** The bacteriology of the gastro-intestinal canal in infancy. A summary, 171.
- Tenney, B., and Chase, H. M.** Mortality after prostatectomy based on a study of 229 fatal results, 437.
- Thorndike, P.** Recent progress in genito-urinary surgery, 786.
- Truesdale, P. E.** Splenic anemia with report of a case, 368.
- Tuttle, A. H.** A case of osteomyelitis with necrosis of the entire femur with spontaneous fracture treated by a high amputation, leaving a boneless yet practical stump for the attachment and working of an artificial limb, 589.
- Vickery, H. F.** Francis Bishop Harrington, M.D., 81.
- von Adelung, E.** A cheap electric heater, 171.
- Washburn, E.** The role of the state sanatorium in the tuberculous problem, 429.
- Watson, F. S.** Report of a case of congenital multiple cystic disease of the kidneys in which one kidney was removed, 169; perforations of the stomach and intestines by foreign bodies that have been swallowed, 622.
- Wells, E. S., and Solomon, H. C.** On the value of the gold sol test (Lange) in cerebro-spinal fluid obtained post-mortem, 398; Varieties of the gold sol test (Lange) in several loci of the cerebro-spinal fluid system; a study of twenty-eight autopsied cases, 625.
- Wesselhoeft, W.** Hospital efficiency from the standpoint of hospital trustees, 778.
- Whittemore, W.** Acute and chronic empyema, 168.
- Williams, F. E.** Psychopathic hospitals and prophylaxis, 933.
- Williams, J. T.** Visceral ptosis. A review, 13.
- Wister, O.** Superstition and the doctor, 357.
- Wolbach, S. B.** Recovery from coccidioidal granuloma, 94.
- Wright, G. H.** Tuberculosis from a dentist's viewpoint, 8.
- Young, E. L.** A new preparation for pyelography, 539; Urethral caruncle, 822.
- Young, E. H.** The emergencies of extra-uterine pregnancy at the Boston City Hospital. An analysis of sixty-two cases, 131.

SUBJECTS.

- Abnormal Blood Pressures**, the significance of, 529.
- Abortion**, legalization of, in France, 604.
- Alcoholic injection** of the internal branch of the superior laryngeal nerve, Irving Sobotky, M.D., 96.
- Allen Treatment** of diabetes, Lewis W. Hill, M.D., and Joseph L. Sherrick, M.D., 696.
- Ambulance construction commission**, 198.
- American College of Surgeons**, 30; Examination for admission to, 39.
- American Social Hygiene Association**, 653.
- Anemia**, splenic; with report of a case, P. E. Truesdale, M.D., 368.
- Anesthesia**, the field for local and spinal in genito-urinary surgery, Arthur H. Crosbie, M.D., 260.
- Anesthetists**, Interstate Association of, 466.
- Angell Memorial Hospital**, 117.
- Animal Experimentation**, defence of in Boston, 651.
- Anatomic and Mechanistic conception** of disease, J. E. Goldthwait, M.D., 881.
- Anatomy**, action of the Association of Anatomists regarding college work in preparation for human, 229.
- Announcement**, 27, 385.
- Annual Discourse**, Some perplexities in modern medicine, Everett A. Bates, M.D., 843.
- Anteposed Uterus**, a few notes on the treatment of, Henry T. Hutchins, M.D., 18.
- Anti-Toxin**, prompt use of diphtheria, 348.
- Antityphus vaccine**, 645.
- Anti-Vaccination arguments**, 654.
- Anti-Vivisection legislation**, 310.
- Atresia**, labyrinthitis following operation for, Gordon Berry, M.D., 700.
- Autotransplantation** of bone for nasal deformity due to syphilis, Louis Arkin, M.D., 672.
- Bacteria**, relation of to the etiology of summer diarrhea in young children, Arthur I. Kendall, 851.
- Bacteriology** of the gastro-intestinal canal in infancy, John Lovett Morse, M.D., and Fritz B. Talbot, M.D., 171.
- Baldwin**, Dr. Henry Cutler, memorial of, 426.
- Bedlam** and its physicians, 599.
- Belgian Physicians' Relief fund**, 38, 80, 120, 159, 199, 240, 283, 319, 356, 391, 427, 465, 501, 538, 572, 611, 655, 692, 728, 767, 805, 842, 880, 924.
- Belgian Red Cross**, 573; meeting for, 566.
- Belgian Scholarship Committee**, 573.
- Bigelow**, Henry Jacob medal and the Boston Surgical Society, 647.
- Biochemistry**, progress in, A. Everett Austin, M.D., 377.
- Birth Rates**, German, 607; French, 79.
- Bladder, Ureter of**, a rare type in women; report of cases, Guy L. Hunner, M.D., 660.
- Bladder, Diverticulum of**, observations upon ten cases of, 365; Some observations upon, Hugh Cabot, M.D., 800.
- Blood Pressure**, during pregnancy, 267; Significance of abnormal, 529.
- Bones, Fractured**, On the fixation of in infants and young children, E. H. Bradford, M.D., and Robert Soutter, M.D., 508.
- Book Reviews**, Allen, Carroll W., local and regional anesthesia, 265; Asher, Philip, chemistry and toxicology for nurses, 65; Autenrieth, William, laboratory manual for the detection of poisons and powerful drugs, 830; Bacon, Charles Sumner, obstetrical nursing, 682; Bainbridge, William Seaman, the cancer problem, 755; Boyd, L. C., state registration of nurses, 913; Brill, A. A., psychoanalysis: its theories and practical applications, 527; Buckley, L. Duncan, cancer, its cure and treatment, 943; Cammidge, P. J., the feces of children and adults, 912; Coulter, John Merle, evolution of sex in plants, 715; Crile, G. W., the origin and nature of the emotions, 913; Delorme, Edmond, *precis de chirurgie de guerre*, 943; Delafield, Francis and Prudden, T. Mitchell, a text-book of pathology, 145; Fitzwilliams, Duncan C. L., a nursing manual for nurses and nursing orderlies, 682; Freyberger, Ludwig, the pocket formula for the treatment of disease in children, 830; Green, Charles M., case histories in diseases of women, including abnormalities of pregnancy, labor and puerperium, 790; Greene, Charles W., Kirke's handbook of physiology, 101; Heitzmann, L., urinary analysis and diagnosis of microscopic and chemical examination, 912; Hemenway, H. B., legal principles of public health administration, 913; Hewitt, C. Gordon, the house-fly, 867; Hoyt, Daniel M., practical therapeutics, 145; Huber, John Bessner, a doctor's viewpoint, 682; Infantile paralysis in Massachusetts, 1907—1912, 682; Jackson, C. - struction of local tuberculosis hospitals, 917; some of the work under the Thomas Thompson trust, 945; the prophylaxis of feeble-mindedness, 947; venereal prophylaxis, 947; a new field for American medical writers, 948; more cosmetic surgery, 948; drug registration, 949.
- Early Marriage**, biologic aspects of, 146; the question of, 381.
- Eminent Men**, production of, 833.
- Employment of Labor**, suggestions in the, Henry Abrahams, 552; T. K. Cory, 551.
- Employment of Patients** in hospitals for the insane, 566.
- Empyema**, acute and chronic, Wyman Whittemore, M.D., 168.
- Enchondroma**. Review of the literature of the subject with report of three cases, Louis A. O. Goddu, M.D., 402.
- Epididymitis**, epididymotomy for, as an out-patient procedure, A. H. Crosbie, M.D., and A. Riley, M.D., 664.
- Epilepsy of Dostojewsky**, a study of, L. Pierce Clark, M.D., 46.
- Extra-Uterine Pregnancy**, emergencies of, at the Boston City Hospital, Ernest Boyen Young, M.D., 131.
- Eugenic legislation**, 268.
- European War**, the care and treatment of the wounded in, Richard Derby, M.D., 693. After-care of Crippled soldiers, 834. An operating room on wheels, 917.
- Familial diseases**, 419.
- Fat Indigestion**, some studies in, Charles Hunter Dunn, M.D., 167.
- Feeble-Mindedness** in Massachusetts, 564.
- Fisher, Theodore Willis**, M.D., memorial resolutions, 117.
- Flexed Scapulae**, late results of surgical treatments for, with a discussion of the subject, Herman W. Marshall, M.D., 812.
- Fly Suppression**, 685.
- Foreign Bodies**, perforations of stomach and intestines by, F. S. Watson, M.D., 622.
- Fractures**, diagnosis and treatment of rare, Wm. Pearce Coues, M.D., 705; on the fixation of, in infants and young children, E. H. Bradford, M.D., and Robert Soutter, M.D., 508.
- French Birth Rate**, 79.
- Gall-Stones**, roentgen diagnosis of, by improved methods, Lewis Gregory Cole, M.D., and Ariel W. George, M.D., 326.
- Gastro-Enterostomy**, posterior, by exact measure, M. P. Smithwick, M.D., 860.
- General Paretics**, somatic characteristics of, Donald Gregg, M.D., 519.
- Genito-Urinary Surgery**, the field for local anesthesia and of spinal anesthesia in, Arthur Hallam Crosbie, M.D., 260.
- German medical efficiency**, 654; birth-rate, 607; medical contributions by, military surgeons, 879.
- Golf Ball accidents**, 602.
- Gold Sol Test**, on the value of, in cerebrospinal fluid obtained post-mortem, H. C. Solomon, M.D., and E. S. Welles, M.D., 398; varieties of, in several loci of the cerebrospinal fluid system: a study of twenty-eight autopsied cases, H. C. Solomon, and E. S. Welles, 625.
- Graves' Disease**, the importance of rest in the treatment of, 456.
- Gunshot Wounds**, unusual, 571.
- Halle, John**: Anatomiste, chirurgien, modernist, Cecil K. Drinker, M.D., 575.
- Hare-Lip Operation**, modification of technic for, W. E. Ladd, M.D., 54.
- Harrington, Francis Bishop**, M.D., Herman F. Vickery, M.D., 81.
- Harrison Bill**, operation of the, 347.
- Harvard Alumni Bulletin**, medical school number of, 349.
- Harvard Expeditionary Unit**, 419.
- Heath Conditions** in Boston in 1914, 69.
- Health Officers**, school for, 158.
- Hemorrhagic Disease** of the newborn, a suggestion in the treatment of, J. C. Hubbard, M.D., 865.
- Hospital Efficiency**, 105.
- Hospital Quiet Zones**, 270.
- Hospital Ship** for deep-sea fisheries, 188.
- Intro-Chemical and Intro-Physical Sects**, 571.
- Illegitimacy**, Boston conference on, 872.
- Immigration** of the insane and mentally defective, 310.
- Immigration Bill**, amendments in, which relate to exclusion and deportation of insane and mentally defective immigrants, 313.
- Infants**, the classification and diagnosis of diarrhea in bottle-fed, 345.
- Insane**, immigration of, 310; immigration bill relating to, 313; some perils confronting state care of the, Charles P. Bancroft, M.D., 247.
- Insane Hospitals**, employment of patients in, 566.
- Insanity** in Massachusetts, 198; does it ever follow operation? 916.
- Intestines**, perforations of, by foreign bodies that have been swallowed, F. S. Watson, M.D., 622; rupture of, Lincoln Davis, M.D., 163.
- Interstate Association of anesthetists**, 466.
- Intravenous Medication** in the seventeenth century, 119.
- Judge Baker and the Juvenile Court**, 683.
- Kidney**, multiple cystic disease of, report of a case, in which one kidney was removed, Francis S. Watson, M.D., 169.
- Labor Clean Milk Bill**, 308, 454, 764, 840.
- Labyrinthitis** following operation for atresia, Gordon Berry, M.D., 700.
- Legalization of Abortion** in France, 604.
- Legislation** on care of tuberculosis in Maine, 30. (See medical legislation).
- Leprosy**, a study of, with especial reference to the pulse and temperature, James A. Honeij, M.D., 580, 629, 668; importance of research in. Significance of pulse rate in the disease, 601.
- Locomotor Ataxia**, compensatory exercises as an aid in the treatment of, H. M. Swift, M.D., 85.
- Lung Disease**, Syphilis and, A. F. Downing, M.D., 898.
- Lymphatic Leukaemia**, in acute infection, after removal of the spleen, James Marsh Jackson, M.D., and William David Smith, M.D., 136.
- Magnetism**, experimental use of for locating needles in the tissues. George H. Monks, M.D., 285.
- Maine**, legislation on care of tuberculosis in, 30.
- Massachusetts Society for Mental Hygiene**, 78.
- Massachusetts State Health Department**, 232; the failure of an important bill of, 348; regulations of, 197.
- Massachusetts Medical Society**. Annual meeting of the supervisors, 952; annual discourse, 843; annual meeting, 724, 916; the annual meeting of the American Medical Association in San Francisco, June 21 to 25, 1915, 689; Dorchester Medical Society, 724; Franklin District Medical Society, 153; Hampshire District Medical Society, 607; Middlesex East District Medical Society, 922; Plymouth District Medical Society annual meeting, 570; program of the 134th anniversary, 837; Shattuck lecture, 881; social service institutes, 799; stated meeting of the council, February 3, 1915, 275.
- Massage**. Some nervous affections in which massage deserves more frequent use, J. W. Courtney, M.D., 483.
- McCollom, John H.**, M.D., a career of professional and public service, 187.
- Medical Association** of the Isthmian Canal Zone, 40.
- Medical Education** in China, 382.
- Medical Examination** of transportation operators, 384.
- Medical Profession** an agent for peace, 646; cooperation with clerical profession, 390.
- Medical Legislation**, miscellaneous matters of, 70, 232, 496; on care of tuberculosis in Maine, 30; four important recent legal decisions, 869.
- Medical Progress**. Ophthalmology, E. W. Clap, M.D., 21; orthopedic surgery, seventh report, R. B. Osgood, M.D., et al., 59, 97; eighth report, R. B. Osgood, M.D., et al., 448, 486; tuberculosis, J. B. Hawes, M.D., and P. C. Bartlett, M.D., 138; pediatrics, J. L. Morse, M.D., and F. B. Talbot, M.D., 171; mental diseases, H. R. Stedman, M.D., Part I, 223; Part II, 262; biochemistry, A. E. Austin, M.D., 377; obstetrics, R. L. DeNormandie, M.D., and J. B. Swift, M.D., 590; dermatology, J. T. Bowen, M.D., 709; genito-urinary surgery, Paul Thorndike, M.D., 786.
- Medical Writers**, American, a new field for, 948.
- Medicine**, the changed position of the profession of, David W. Cheever, M.D., 473.
- Memorial Resolutions**, Charles Sedgwick Minot, M.D., 116; Theodore Willis Fisher, M.D., 117; George Dexter Bullock, M.D., 117; James Gregory Mumford, 354; Hasket Derby, M.D., 354; Henry Walter Wood, M.D., 655.
- Mental Diseases**, report of progress in, Part I, Henry R. Stedman, M.D., 223; Part II, 262.
- Mental Defect**, border-line cases of, with special reference to hysterical symptoms, Chester C. Beckley, M.D., 510.
- Mental Defectives**, immigration of, 310; immigration bill relating to, 313.
- Mental Examination**. Program and directions for the mental examination of asocial, psychopathic and doubtful subjects, Rose S. Hardwick, 817, 861, 906, 935.
- Mental Hygiene**, Massachusetts Society for, 78.
- Metallic Substances**, location of, in the tissues, 119.
- Military Nostalgia**, 39.
- Milk** legislation and investigation in Massachusetts, 534; Differentiation of human and cow's milk by color tests, Richard S. Eustis, M.D., 92; Labor clean milk bill, 308, 454, 840; the milk supply and bovine tuberculosis, 871.
- Minot, Charles Sedgwick**, M.D., W. T. Porter, M.D., 167.
- Miscellaneous Matters of Medical Legislation**, 70, 232, 496.

- Miscellany.** Belgian physicians' relief fund, 38; military nostalgia, 39; examination for admission to American College of Surgeons, 39; the medical association of the Isthmian Canal zone, 40; United States civil service examination, 40; the transfer of the quarantine station, 76; British Red Cross hospitals, 77; Massachusetts Society for Mental Hygiene, 78; the French birth-rate, 79; Belgian physicians' relief fund, 80; memorial resolutions, 116; Charles Sedgwick Minot, M.D., 116; Theodore Willis Fisher, M.D., 117; George Dexter Bullock, M.D., 117; Angell memorial hospital, 117; Larrey at Waterloo, 118; intravenous medication in the seventeenth century, 119; changes in the Medical Corps, U. - Nurse**, Red Cross, patriotic and humane service of, Miss Mabel T. Boardman, 503.
- Nursing Question**, 189.
- Obituaries**. Dudley P. Allen, M.D., 157; Henry Cutler Baldwin, M.D., 388; Thomas Bryant, F.R.C.S., M.Ch., M.D., 279; Sir Thomas Smith Clouston, M.D., 651; Edward Russell Cogswell, M.D., 38; Lieut.-Col. Charles Dalton, M.D., 878; William Murray Dobie, M.D., 534; James Brainerd Field, M.D., 651; Michael Freebern Gavin, M.D., 840; Albert van Gehuchten, M.D., 115; Sir William Richard Gowers, M.D., F.R.C.P., F.R.S., 877; Samuel Wood Lohmald, M.D., 422; Friedrich Loeffler, M.D., 724; John Hildreth McCollom, M.D., 953; Right Hon. Sir George Turner, F.C.M.G., M.D., LL.D., 461; Emery Lincoln White, M.D., 725.
- Obstetrics**. Report on obstetrics, Robert L. DeNormandie, M.D., and John B. Swift, M.D., 590; organized obstetric and pregnancy care in Massachusetts, 647.
- Occupational Disease** and the public health, Donald B. Armstrong, M.D., 51; control of, 868.
- Ophthalmology**, progress in, Edmund W. Clap, M.D., 21.
- Opium Traffic**, early history and suppression of, 315.
- Orthopedic Surgery**, seventh report of progress in, Robert B. Osgood, M.D., Robert Soutter, M.D., Hermann Bucholz, M.D., Harry C. Low, M.D., Murray S. Danforth, M.D., 59, 97; eighth report of progress in, Robert B. Osgood, M.D., Robert Soutter, M.D., Hermann Bucholz, M.D., Harry C. Low, M.D., Murray S. Danforth, M.D., 448, 486.
- Osteomyelitis**, a case of with necrosis of the entire femur with spontaneous fracture treated by a high amputation, leaving a boneless yet practical stump for the attachment and working of an artificial limb, Albert H. Tuttle, M.D., 589.
- Out-Patient Work**, note on the recent extension of in Massachusetts hospitals for the insane, A. Warren Stearns, M.D., 553.
- Ovarian Transplantation** with report of a case of implantation into the uterus with resulting pregnancy, Malcolm Storer, M.D., 41.
- Pan-American Medical Congress**, the seventh, 531.
- Parotid Fistula** following mastoid operation, Philip Hammond, M.D., 25.
- Perforations** of the stomach and intestines by foreign bodies that have been swallowed, F. S. Watson, M.D., 622.
- Pre-Operative Diagnosis** of tubercular mesenteric and retroperitoneal glands, Edw. H. Risley, M.D., 253.
- Perineal Prostatectomy**, report on some cases of, F. G. Balch, M.D., 507.
- Philippine civil service examinations**, 239.
- Physical Examination**, the importance of the, to those attendant upon infants, 108.
- Physical Types** in the human being, 914.
- Plastic Surgery** in prociencia with report of 25 cases, Florence W. Duckering, M.D., 292.
- Pneumonia**, the treatment of in children. Report of 101 consecutive cases, Harold W. Dana, M.D., 58.
- Poliomyelitis**, investigation of in Vermont, 425.
- Posterior Gastro-Enterostomy**, by exact measure, M. P. Smithwick, M.D., 869.
- Pott, Percival**, his times and his work, Robert W. Lovett, M.D., 807.
- Pregnancy Care**, the importance of, 385; organized obstetric and pregnancy care in Massachusetts, 647; care of prospective mothers, A. B. Emmons, 2nd, M.D., 618.

- Procidentin**, plastic surgery in, with report of 25 cases, Florence W. Duckering, M.D., 292.
- Production of Eminent Men**, 833.
- Profession of Medicine**, changed position of, David W. Cheever, M.D., 473.
- Professorship**, proposed of psychiatry, 684.
- Progressive Neuro-Muscular Atrophy** (peroneal type of Charcot, Marie and Tooth): with report of three cases in a family without heredity, Floyd F. Hatch, M.D., 393.
- Prophylaxis**, the, of feeble-mindedness, 947.
- Prospective Mothers**, care of, Arthur B. Emmons, 2nd, M.D., 618. (See pregnancy care).
- Prostectomy**, mortality after, based on a study of 229 fatal results, Benjamin Tenney, M.D., and Henry M. Chase, M.D., 437; a report of some cases of perineal, F. G. Balch, M.D., 507.
- Prostitution and venereal disease**, 231.
- Psychiatry**, proposed professorship of, 684.
- Psychopathic Hospitals and prophylaxis**, Frankwood E. Williams, M.D., 933.
- Psychopathic Subjects**, normal-looking brains in, E. E. Southard, M.D., and M. M. Canavan, M.D., 124; program and directions for the mental examination of, Rose S. Hardwick, 817, 861, 906, 935.
- Ptosis** in children, 28; corsets and sacro-iliac strain, Robert M. Green, M.D., 587; visceral, a review, John T. Williams, M.D., 13.

- Pulmonary Tuberculosis** see tuberculosis.
- Putnam, Charles Pickering, M.D.**, W. E. Robbins, M.D., 84.
- Pyelography**, a new preparation for, Edward L. Young, Jr., 539.
- Pyloric Tumor**, congenital, 190; the significance of x-ray examination following operation for, Charles L. Scudder, M.D., 166.
- Quarantine Transier**, the question of Boston, 495; federal or local administration of maritime quarantine, 185, 29, 66, 76, 531.
- Rabies**, a case of human, Harry Linenthal, M.D., 221; in China, A. C. Reed, 901.
- Recurrent Vomiting**, urinary acidity and beta-oxybutyric acid determinations in, Willard S. Parker, M.D., 164.
- Red Cross**, nurse, patriotic and humane service of, the Miss Mabel T. Boardman, 503; British hospitals, 77; Belgian, 573; meeting for, 566.
- Renal Infections**, William H. Robey, Jr., M.D., 217.
- Röntgen**, diagnosis of gall-stones by improved methods, L. G. Cole, M.D., and Ariel W. George, M.D., 326. (See x-ray).
- Rotch, Thomas Morgan, M.D.**, C. H. Dunn, M.D., 82.
- Rupture of Intestine**, two cases of, Lincoln Davis, M.D., 163.
- Ruptured Tubal Pregnancy**, treatment of, 147.
- Rutland State Sanatorium**, admission to, 149.
- Sacro-Iliac Strain**, corsets, ptosis and, Robert M. Green, M.D., 587.
- Sanatoriums**, state, role of, in tuberculosis problem, Elliott Washburn, M.D., 429; enforcement of law for local tuberculosis, 457; construction of local, 917.
- Scapulae, Flexed**, late results of surgical treatments for, with a discussion of the subject, Herman W. Marshall, M.D., 812.
- Scholarship** in medicine, Theobald Smith, M.D., 121.
- School for health officers**, 158.
- School Lunches**, health aspects of, 493.
- Seventeenth Century Letters**, medical extracts from, 423.
- Sewage**, disinfection of from trains and steamers, 108.
- Shattuck Lecture**, an anatomic and mechanistic conception of disease, J. E. Goldthwait, M.D., 881.
- Smith, Dr. Theobald**, complimentary dinner to, 420, 873.
- Social Service institutes**, 759.
- Society Reports**, American Association of Immunologists, meeting of June 22, 1914, 555; American Urological Association, fall meeting of the New England branch, November 30, 1914, 676; Boston Dispensary, one hundred and eighteenth annual meeting, held January 21, 1915, 638; The Boston Surgical Society, meeting of February 1, 1915, 522, meeting of March 1, 1915, 638; Carney Hospital clinical meeting, 911; the College of Physicians of Philadelphia, meeting of November 4, 1914, 178, meeting of November 23, 1914, 201, meeting of December 14, 1914, 452, meeting of January 6, 1915, 525, meeting of February 3, 1915, 825; Massachusetts Medical Society, (See Massachusetts Medical Society heading.); Neurological Institute, clinical conference of, meeting of February 25, 1915, 828, meeting of November 12, 1914, 175, meeting of January 21, 1915, 341, meeting of March 25, 1915, 939; New England Otological and Laryngological Society, meeting of January 19, 1915, 714; New England Pediatric Society, meeting of October 23, 1914, 102; meeting of December 4, 1914, 180; meeting of January 20, 1915, 752; the Philadelphia County Medical Society, meeting of November 25, 1915, 142; meeting of November 11, 1914, 63; the Suffolk District Medical Society, meeting of the surgical section, held January 6, 1915, 789.
- Spheno-Palatine Ganglion**, injection of, 915.
- Spinal Anesthesia**, the field for in genito-urinary surgery, Arthur H. Crosbie, M.D., 260.
- Spleen**, lymphatic leukemia in acute infection, after removal of, James M. Jackson, M.D., and W. D. Smith, M.D., 136.
- Splenic Anaemia** with report of a case, P. E. Truesdale, M.D., 368.
- Starvation Method** versus gradual carbohydrate reduction as a time saver in the treatment of diabetes, Henry A. Christian, M.D., 929.
- State Department of Health**, regulations of, 197; health department, 232; failure of an important bill, 348.
- State Sanatorium**, the role of the, in the tuberculosis problem, Elliott Washburn, M.D., 429.
- Stomach**, a study of disturbances of, H. F. Hewes, M.D., 286, 338, 370, 406; perforations of by foreign bodies that have been swallowed, F. S. Watson, M.D., 622, the clinical use of the water meal in determining the secretory and motile powers of, A. Everett Austin, M.D., 857.
- Streptococcus Sore Throat**, epidemic of, 686.
- Stuttering**, the nature of, 834.
- Sub-Mucous Resection** as a means of obliterating superficial blood-vessels, Joseph Prens, M.D., 138.
- Superstition and the doctor**, Owen Wister, 357.
- Symposium on tuberculous cervical adenitis**, 1.
- Syphilis**, 495; the menace of to the clean-living public, J. Harper Blaisdell, M.D., 476; dangers from, Abner Post, M.D., 550; and lung disease, Andrew F. Downing, M.D., 898.
- Tabs**, exercise in the treatment of, 106.
- Thackeray's physicians**, William Pearce Cones, M.D., 202.
- Thomas Thompson Trust**, some of the work under the, 945.
- Todd-Harmon Method**, partial tenotomies by, Holbrook Lowell, M.D., 56.
- Tonsils**, adenoids, relation of and other throat conditions to tuberculous cervical adenitis, George L. Richards, M.D., 1.
- Transplantation of tissues and organs**, 69; ovarian transplantation, 41.
- Tubal Pregnancy**, ruptured, treatment of, 147.
- Tuberculin skin reactions**, a study of children with, Orville F. Rogers, Jr., M.D., 161.
- Tuberculosis**, legislation on care of, in Maine, 30; "remedies" that are worthless, 652; from a dentist's viewpoint, George H. Wright, D.M.D., 8; in its relation to the handling of food, Cleveland Floyd, M.D., 549; progress in, John B. Hawes, 2nd, M.D., and P. Chailis Bartlett, M.D., 138; remarks on the diagnosis and treatment of pulmonary tuberculosis, Bayard T. Crane, M.D., 433; factors in the duration of pulmonary, 455; work in Connecticut, its development in the last decade, and its future needs, D. R. Lyman, M.D., 657; local care of advanced, 309; enforcement of law for local institutions, 457; bovine and milk supply, 571; the California climate and the treatment of, 578; cutaneous, report

- of a case of folliculitis and erythema induratum, J. H. Bufford, M.D., and C. G. Lane, M.D., 825; role of the state sanatorium in the problem, Elliott Washburn, M.D., 429; hospitals, construction of, 917.
- Tuberculous Cervical Adenitis**, symposium on, 1; relation to the tonsils, adenoids and other throat conditions to, George L. Richards, M.D., 1; treatment of, Henry D. Chadwick, M.D., 5; treatment of, John B. Hawes, 2d, M.D., 6; from a dentist's viewpoint, George H. Wright, D.M.D., 8.
- Tuberculous Infection** as a disease entity, G. T. Palmer, M.D., 904.
- Tumors**, of the neck, differential diagnosis and indications for treatment of, Oliver C. Smith, M.D., 208.
- Typhoid Fever** in the cities and towns of New York during the last decade, and disinfection by chlorination of public water supplies in the state, 563.
- Typhus Fever**, an antityphus vaccine, 645.

HONORARY FELLOWS

1892 Goodale, George Lincoln, 5 Berkeley St., Cambridge, Mass.

ACTIVE AND RETIRED FELLOWS

JANUARY 1, 1915

NOTE.—The date preceding the name is that of admission. A date following, preceded by a †, denotes year retirement. The first name of city or town is the legal residence; the street and number are the office address.

A letter in place of a given name not followed by a period is not an initial. It is a letter adopted by the individual instead of a name to distinguish him or her from others, or for the sake of euphony.

A

- 1884 Abbe, Alanson Joseph.....Fall River. 375 Rock St.
1910 Abbe, Elizabeth Morrison..Roxbury (Boston).
47 Pilgrim Road.

NOTICE TO FELLOWS OF THE SOCIETY.

THE BOSTON MEDICAL AND SURGICAL JOURNAL, the Official Organ of the Society, is issued weekly and sent only to those who have paid their assessments, and to such Honorary and Retired Fellows as may apply for them to the Librarian.

Fellows who fail to receive the Publications should notify the Librarian at once.

Fellows are requested to send prompt notice to the Librarian of changes of residence or office address or of errors noted in this Directory.

EDWIN H. BRIGHAM, M.D.,

Librarian.

I.

RELATION OF THE TONSILS, ADENOIDS AND OTHER THROAT CONDITIONS TO TUBERCULOUS CERVICAL ADENITIS.

BY GEO. L. RICHARDS, M.D., FALL RIVER, MASS.

For the proper understanding of this subject a knowledge of the anatomy and of the relationship of the lymphatic drainage of the tonsils, the adenoid tissue and the pharyngeal region to the cervical lymphatics is necessary. Whereas considerable space is given to this subject in various

text-books of anatomy, most of it seems to be based on the original work of Sappey, which was done on children many years ago, and that of Poirier, Cuneo, Delamere and Most. It is stated in many monographs on the subject that the tonsils drain into the superficial and deep lymphatics, but I am unable to find any valid, anatomical statement for their drainage into the superficial lymphatics. The superficial lymphatics drain the areas of the anterior part of the mouth and tongue, and then pass into the deeper chain, while all that is posterior, including the entire pharynx, the post-nares, the upper pharynx, the tonsils and the base of the tongue, drain into the deep lymphatics of the jugular chain, of which there are two or three sets.

Briefly, this anatomy is as follows:—There are two principal retropharyngeal glands, one on each side of the median raphe, at the junction of the posterior and lateral surfaces of the pharynx, corresponding to the situation of the arch of the soft palate, with sometimes three or more additional lymph nodes on one side or the other. These glands correspond to the general situation of retropharyngeal abscesses, these being invariably found on one or the other side of the median line. They receive the lymph coming from the mucous membrane of the nasal fossae, and adjacent cavities, and drain into the upper glands of the internal jugular chain, passing behind the vessels and the nerves. The general lymphatic drainage of the pharynx ends either in the retropharyngeal glands or the internal jugular chain. The glands of this chain also receive the lymph from the internal group of the sternomastoid glands. The lymphatics from the tonsil appear to drain into the posterior lymph glands of the tongue, thence into two lateral trunks, thence passing down the lateral wall of the pharynx terminating in large glands of

* No paper received for publication.

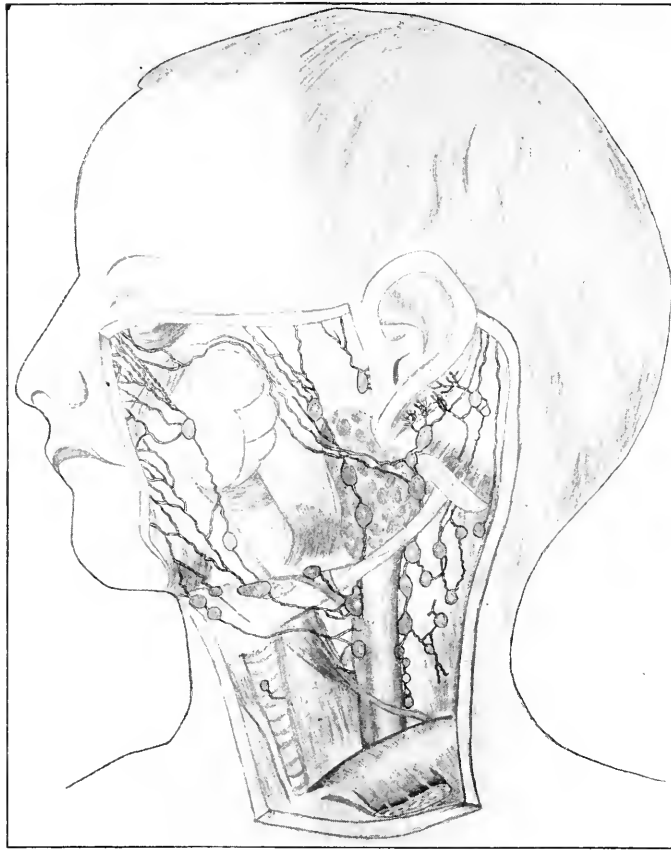

FIG. 1.—General scheme of the lymph-stream of the outer nose, the face and the side of the head, together with the lymphatic gland groups of the head and neck. (After Most.)

the internal jugular chain behind the posterior belly of the digastric. This is the principal meeting place of the neck lymphatics. A not inconsiderable number of the lymph vessels go directly from the posterior pharyngeal wall to the deep glands of the neck and the jugular region. The adenoid area drains into the posterior wall of the pharynx, which is the chief collecting point of the lymphatics of the pharynx both from the roof of the pharynx, and from the posterior and side walls, and from the Eustachian tube. The lymphatics of the larynx drain into the glands arranged along the internal jugular chain, the substerno mastoid glands being the principal terminus. The lymphatic glands of the lung form a rich network joining together up to the point of entrance of the lung where they become superficial. They pass through several pulmonary lymph glands forming by their union broncho mediastinal trunks. These course along the trachea to the lower portion of the neck, and finally open at the venous confluence or into the thoracic duct on the left, and on the right directly into the subclavian, or at the junction of the jugular and subclavian.

The tonsil itself develops as an ingrowth of endothelium from the second bronchial pouch. According to Gordon Wilson, in origin it is in

line with the thymus and the thyroid, and is not a pure lymphoid structure. It begins to develop about the fourth month of embryonic life, and matures about puberty. It probably has some protective function in the early years of life as the experimental work performed by G. H. Wright and many others has shown. The argument that because no deleterious results follow enucleation, the tonsil is of no value, and should be removed in every case, is not a good one, since its period of greatest functional activity is before puberty. Tubercular adenitis is usually a localized tubercular affection most frequent in childhood from the sixth to the fifteenth year, although it may occur in early infancy, and seems to have some relationship to diseased tonsils, adenoids and general pharyngeal disturbance. It has repeatedly been demonstrated by Wood and others that tubercle bacilli can be made to invade and pass through the faucial tonsil without producing tuberculosis of the tonsil itself. The same is probably true of other portions of the lymphoid area whose anatomy we have been considering. When we come to estimate the number of cases of tonsils which of themselves are actually diseased, we find the number varying from one or two per cent. up to ten, according to the experience

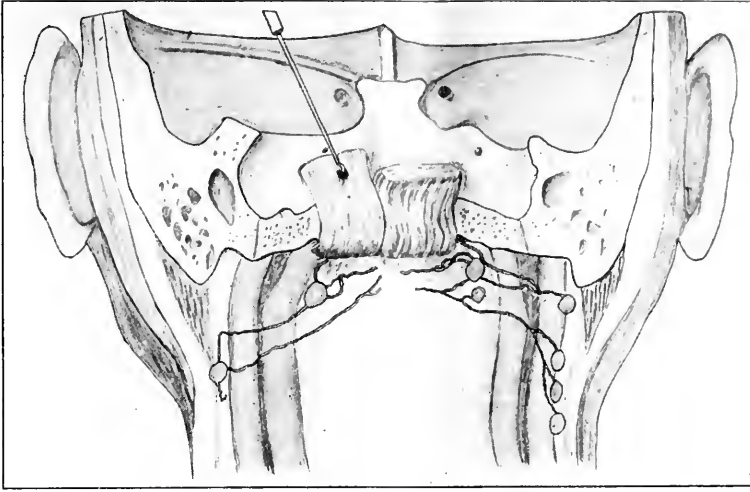

FIG. 2.—Lymph vessels and glands of the retropharyngeal space as seen posteriorly. (After Most.)

of the individual observer. Tubercle bacilli have been extremely hard to demonstrate in the tonsil, hence the question of the presence or absence of tubercular disease has had to depend principally upon histologic findings. A sufficient number of observations have been made to demonstrate that tubercular adenitis is not necessarily accompanied by a tubercular tonsil, but seems to have its source with the tonsils as the port of entrance of the trouble even though they themselves may not have been diseased. In one instance I removed the adenoids in a girl of twelve, some years later she had a severe attack of cervical adenitis, with broken down glands, which on removal, were found to be tubercular. The tonsils were removed at this time, and the individual has been perfectly well ever

since. She is a strong and robust woman, and never had any cough. She married, the adenoids were removed from her child, and then this child developed adenitis with broken down glands, but without signs of any general tuberculosis. The glands were removed, and later the tonsils also, with the result that the child is now in perfect health, more than a year having elapsed since the last operation. I do not think there was any direct heredity in this instance, but in each case the infection occurred through the faucial tonsils. Certain it is that after removal of the faucial tonsil in many children previously suffering, to a greater or less degree, from enlarged cervical glands, these glands disappear and are no longer palpable to the finger. In a recent review clinic, held to determine the

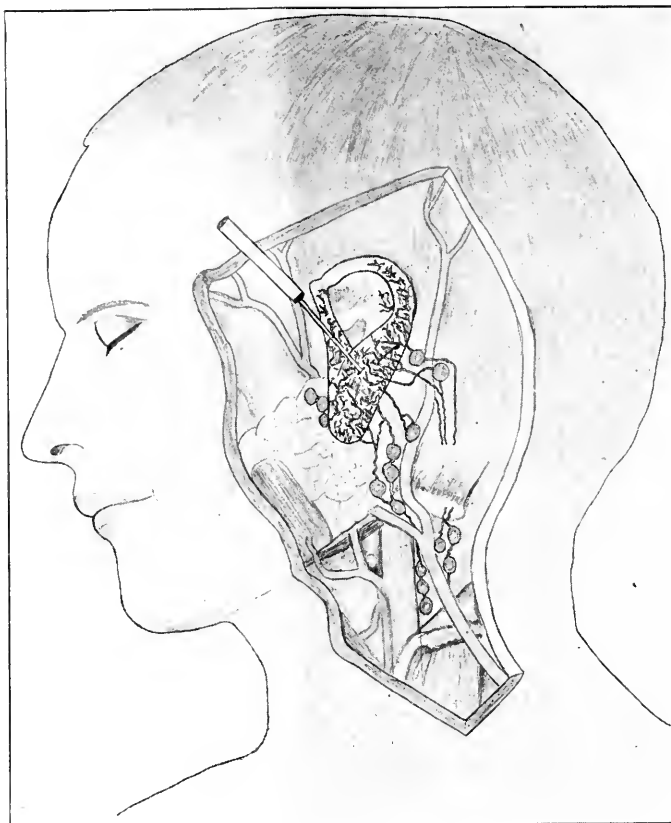

FIG. 4.—Lymph vessels of the external ear and the glands of the same region. In front of the ear are the two anterior auricular glands in the niche between the parotid and the anterior wall of the external canal. Behind the ear are the mastoid glands and below the ear five infra-auricular glands. The deep neck glands along the internal jugular are also shown. (After Most.)

final results, in a series of cases operated on for tonsils and adenoids, something over 100 in number, it was found that the cervical lymph glands, were, as a rule, felt not at all, or to only a slight degree. Many of these children did have enlarged lymph glands at the time of operation. Although it is impossible to determine in the individual case whether the tonsil is the source of the adenitis or whether its removal will cause a disappearance of the enlarged glands, I am inclined as the result of my own experience and that of others, to recommend that in all cases of cervical adenitis the tonsil be removed as the first procedure. If the glands are broken down, and an operation upon them has to be performed, then the tonsil should be removed at the same time. That the removal of the tonsil removes all source of possible danger of infection of the cervical lymph glands is not claimed, since anatomical studies already referred to have shown that the entire area of the middle ear, Eustachian tube, superior, posterior and lateral pharyngeal wall, the tonsils, base of the tongue, and posterior nares all have their lymphatic drainage area into the cervical lymph glands. The tonsil, however, being large, and situated in

the back of the mouth where it is very subject to infection and to pressure during the act of eating and swallowing, is probably the greatest offender. As the tonsil is such a possible portal of infection, and as its removal seems to be followed by no deleterious effects upon the organism, and as it is very likely to be a source of entrance for the infection of rheumatism, I should advise its removal in all cases of cervical adenitis, and in all children whose parents give a history of having had cervical adenitis. At the same time, one cannot say with positiveness that the removal of the tonsil will either cure or prevent cervical adenitis. Here, as in other departments of medicine, each case must be judged on its own merits. One can always reassure the parents of such children that in all probability the cervical adenitis is not an accompaniment of a general pulmonary tubercular process, since the lymph glands of the lung drain directly into the blood stream, the drainage from the two areas having no direct meeting-place, unless near the point of final entrance into the general blood stream. It, of course, cannot be denied that there is some possibility of general infection from the entrance into the general blood stream of bacilli from the infected

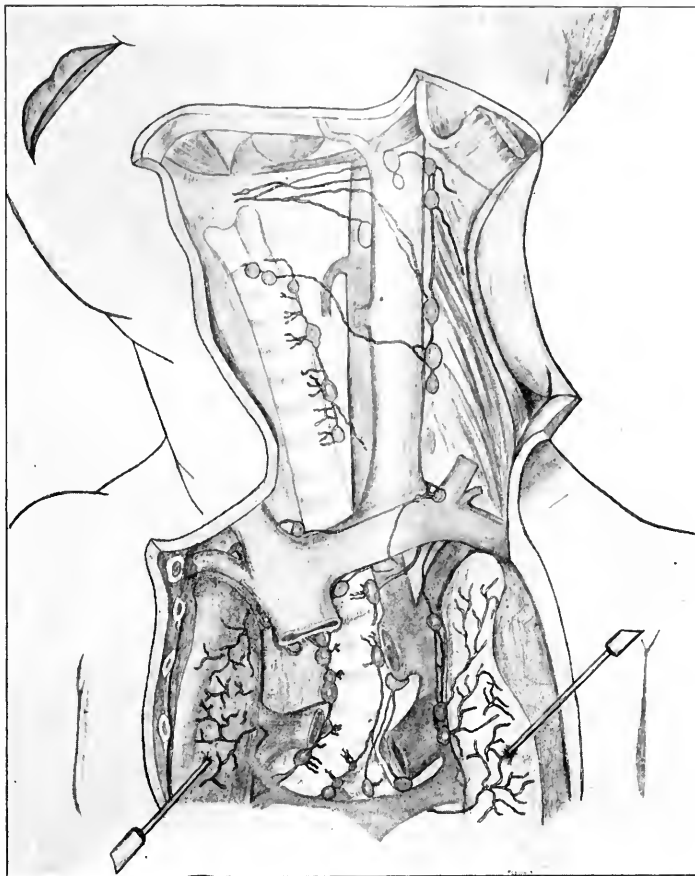

FIG. 5.—The lymph channels and glands in the region of the larynx, trachea and tracheobronchial glands, with their course from the trachea and the lungs. (After Most.)

cervical lymph glands. Practically, however, the process is usually limited to the area involved. It is not probable that all enlarged cervical lymph glands are tubercular, presumably about 80% of them are.

[I have to acknowledge in the preparation of this article my special indebtedness to the volume on the "Lymphatics" of Poirier, Cuneo, and Delamere, and to the articles entitled "Der Lymphgefäßapparat des Kopfes und des Halses," by Professor August Most, published in Vol. I "Handbuch der speziellen Chirurgie des Ohres und der oberen Luftwege," edited by Katz, Preysing and Blumenfeld, from which article the illustrations here presented have been redrawn.]

II.

TREATMENT OF TUBERCULOUS CERVICAL ADENITIS.

BY HENRY D. CHADWICK, M.D., WESTFIELD, MASS.

Superintendent, Westfield State Sanatorium.

IN March, 1910, a young woman 23 years of age, was transferred from the Massachusetts General Hospital to the Westfield State Sanatorium. One of the assistant resident physicians

signed the application blank on which he made this note,—

"Tuberculous cervical adenitis; operation not advisable. Signs of tuberculosis present at right apex."

Briefly the history of the case was as follows:—

The glands of the left cervical region began to enlarge four years ago. Those of the right side two years later. Recently she noticed considerable loss of strength and her weight was fourteen pounds below normal.

Physical examination showed that the anterior, posterior and sub-maxillary groups of glands were all involved. The swelling was so extensive that the neck had lost all its natural contour.

While at the hospital a small gland was excised for examination and a pathologist reported that it was tuberculous.

There was slight consolidation of the right apex, without signs of active disease.

For the first week following her admission, her temperature varied from 100 to 103, and then gradually declined until it reached normal in about six weeks. During this time there had been little decrease in the size of the enlarged glands. After her temperature had been normal

for about a month tuberculin treatment was commenced. The initial amount given was one millionth of a milligram. The dosage was cautiously increased up to a maximum of ten milligrams. The swollen glands steadily reduced in size during the treatment.

She was discharged as a patient in November, 1910. At that time her neck had a normal appearance and only a few of what had been the largest glands could be felt. Her general condition was very good, and she was given work as a ward maid. We continued the tuberculin several months longer, while she was thus employed.

The results in this case were so good that all subsequent patients, as they were admitted, were given tuberculin treatment if they had enlarged glands and their pulmonary disease was not so active as to contraindicate its use. I have had but a comparatively few adults with tuberculous adenitis who were suitable cases for this treatment. Each one has responded satisfactorily to tuberculin, except one out-patient. This woman came for treatment twice a week and continued her usual occupation. Although she came faithfully for the injections until a dose of ten milligrams was reached, there was no apparent decrease in the size of the glands. I am of the opinion that had this patient been under sanatorium conditions while being treated, a satisfactory result might have been obtained.

One other patient had cervical adenitis so extensively that it made operation inadvisable. She had been referred to the sanatorium from the out-patient department of the Massachusetts General Hospital. This girl had been at the sanatorium two different periods for a few months each, and left against advice each time. Tuberculin was given regularly while at the sanatorium, and continued at irregular intervals at the out-patient department of the hospital. In this case much good has been accomplished, but probably some of the larger fibroid glands will later need to be excised.

Another young woman had a marked enlargement of the right posterior cervical group. Some of the glands had become caseous, broken down, and there was a discharging sinus. Four months' treatment with tuberculin was without apparent effect. The enlarged glands were then excised, and the tuberculin continued. The wound healed by first intention. After her discharge as a patient, she worked at the sanatorium for two years as a domestic. Her health was excellent, although at one time a swelling appeared near the sight of the old scar, which, after resuming tuberculin medication, soon disappeared.

Many of the children admitted at Westfield have tuberculous cervical glands. Not many are noticeably large, but they can be readily felt on examination. Almost invariably these children also have enlarged bronchial glands, as evidenced by impaired resonance between the scapulae.

As a routine part of their treatment, we put these patients on bacillen emulsion, if they do not have more than a degree of temperature, or other signs of active pulmonary disease.

The initial dose is one millionth of a milligram, and the course of treatment extends over a period of about six months, until we reach ten milligrams. This maximum could be reached in a shorter time, but I feel that a small dose given over a longer period is more effective, and can be given in this way without causing reactions.

The result of treatment in these children is very satisfactory. The cervical glands decrease perceptibly in size, and the area of dullness over the hilus becomes smaller and less pronounced.

The longer the tuberculous disease has existed in a gland the slower will be the effect of treatment.

Resolution must necessarily be limited if fibroid changes have taken place. Suppuration has not occurred in any case where it did not exist prior to treatment.

One young girl having multiple tuberculous ulcerations of the skin and numerous involved glands showed marked improvement as soon as we began to administer tuberculin. She is still under treatment with every indication that the ulcers will heal and that the enlarged glands will disappear.

In a few instances where patients have developed adenitis while in the sanatorium, we have invariably found that instituting tuberculin treatment will prevent further swelling and cause that which has occurred to undergo prompt resolution.

This experience leads me to the conclusion that surgical interference is only necessary to remove such glands as have become caseous, or fibroid. Extensive dissections are unnecessary in these cases, as the small recently diseased glands that are left will disappear under the influence of tuberculin treatment.

IV.

THE TREATMENT OF TUBERCULOUS CERVICAL ADENITIS.

By JOHN B. HAWES, 2D, M.D., BOSTON.

I WISH it understood that I am making no special plea for tuberculin in the treatment of tuberculous adenitis. I believe that tuberculin does a certain amount of good in certain cases. With proper handling it does no harm. I also wish it understood that I am likewise not opposed to proper surgery. I feel very strongly that if we could multiply over this country men of the skill and experience in this line of Judd of Rochester, Dowd of New York, and Stone and Porter of this city, we might not need any tuberculin. What I want to emphasize strongly, however, is that surgery in many hands cannot do all we ask of it when dealing with

a tuberculous infection. In every instance the operation, be it large or small, should be regarded as but an incident in a course of treatment, the most important part of which comes before and after the operation; and furthermore, it should be borne in mind that it is a human being and not merely a neck which is being treated. The average doctor cannot do a good dissection of the neck; the radical operation, so-called, in most hands is not radical, and often does not cure.

The treatment of tuberculous adenitis has undergone a curious change during the past fifteen years. At first no pathological condition was looked upon as more properly belonging to the surgeon than enlarged tuberculous glands in the neck. The operation for "radical excision of glands of the neck" was a very common one in our hospitals and almost invariably it was entered in the record books that the patient was "discharged cured." It was indeed a curious state of affairs, because in practically no case was the operation radical in the strict interpretation of the word, and, as I believe I can demonstrate, it did not cure in a large proportion of cases, while in many of those in which an apparent cure resulted, large and disfiguring scars remained.

Next, late in the last decade, there swept over this country and Europe a wave of enthusiasm for the use of tuberculin as a cure for all forms of non-pulmonary tuberculosis. Surgery was decried; common sense methods of hygienic treatment were neglected, while many physicians, imbued with the tuberculin idea, became mere "injectors," as Nathan Raw scoffingly calls them. There is no need of dwelling upon the narrow mindedness of this attitude.

Finally, at the present time, a sounder and saner therapy has developed. Surgery, conservative or, in rare cases, radical, depending on the surgeon's skill or lack of it, has its place; tuberculin in some cases does wonders, in others it plays a lesser rôle and at all events, in competent hands can do no harm. Hygienic measures including out-door sleeping, proper diet, exercise and rest, baths and heliotherapy are given their proper place as the basis of all treatment in all forms of tuberculosis while, of the greatest importance, the cleaning up of portals of entry and removal of foci of infection such as carious teeth, diseased tonsils and adenoids are recognized as an essential part of treatment for this condition.

First, as to surgery in tuberculous adenitis, it is evident even to the casual observer, that in this city at least, and I believe elsewhere, the so-called "radical operation" is not performed nearly as frequently as it was ten years ago. The only possible reason for this must be that the result obtained did not justify its continuance. To make a complete dissection of the neck and to remove all traces of diseased glands is a difficult and well nigh impossible task. Were it possible to confine this operation to a few spe-

cially trained surgeons in every large city our results might be better; as it is, the operation is looked upon far too lightly and is entered upon without the skill, experience and training necessary for successful results. The tendency for surgeons to become trained and to devote special attention to diseases of one part of the body will, I hope, lead to better conditions.

I am far from maintaining that wholesale removal of glands is not the best procedure in certain instances. Where there are large, discrete isolated masses, without suppuration, a simple incision with removal of these masses *without any attempt* to do a complete dissection is frequently a measure of greatest value. In other less favorable cases, the removal of part of a large mass will often enable the patient to handle the rest of the diseased tissue himself. These operations, however, are not radical ones.

Conservative surgery has a far wider sphere of usefulness. The incision of abscesses and evacuation of pus, the curettage of an abscess cavity and removal of its contents, patient and detailed care in draining sinuses, etc., are regarded as surgical drudgery; careful attention paid to the details of this work, however, play a large part in producing good results.

The use of tuberculin will probably be confined to specialists and will never become common among general practitioners. While among the 250 cases of tuberculous adenitis that have been under my care during the last five years in whom tuberculin has been a part of the treatment, I have met with some discouraging results. I feel that on the whole tuberculin has accomplished a great deal of good and *in no case has done any harm*. The reasons for failure or unsatisfactory results with tuberculin have been chiefly as follows:

a. The length of treatment and consequent effect on the patients who frequently become discouraged and drift away before any results can be expected.

b. Poor general condition of the patient which prevents any response to tuberculin.

c. The presence of active pulmonary tuberculosis. I am unwilling to give tuberculin to such patients except under absolute supervision in a sanatorium or elsewhere.

d. Certain isolated, walled off, discrete masses of glands in adults or young adults. Surgical measures are best for these cases.

Those patients, on the other hand, who have done well with tuberculin or accompanying the use of tuberculin group themselves as follows:

A. A large group of patients who have been operated upon more or less extensively for tuberculous glands. I am firmly convinced as the result of a fairly wide experience in such cases that tuberculin is a great help not only in curing immediate trouble but in preventing recurrences.

B. Patients, adults or children, with discharging sinuses which have persisted in spite of

proper treatment. Tuberculin has been a great help in closing such sinuses.

C. Children with more or less scattered glands, making operation inadvisable, living under proper hygiene, who despite this seem to be at a standstill or to be going slowly down hill and whose glands are gradually enlarging. It is in this class of cases that tuberculin has produced brilliant results.

D. Comparatively rare cases in adults where a large mass of glands, often smooth, hard and immovable, is surrounded by much periglandular tissue. I have not infrequently seen such masses literally melt away under tuberculin.

Finally, I would again emphasize the fact that tuberculin should be looked upon with respect as a potent agent for good or for evil in all forms of tuberculosis. The chief criterion in its use should be not to do harm.

Of hygienic measures little need be said. I may safely take it for granted that the medical profession of this State is fully alive to the fact that not only pulmonary but all forms of tuberculosis demand fresh air day and night, rest and exercise in proper proportions, good food well prepared, baths, and sunlight and all that constitutes what I may call "right living." The care of tuberculous adenitis demands all of these. They are the foundation on which successful treatment rests.

Last, not only in helping to cure, but of more importance, in preventing this condition, the hygiene of the mouth and throat is most essential. Diseased tonsils whether large or small, adenoid growths and carious teeth must receive their due attention. The details of how best to do this may well be left to others better qualified than I.

On closing, two thoughts seem to me to be of prime importance—namely, that the physician remember always that cervical adenitis is but a form of tuberculosis and that he is treating not a few enlarged glands of the neck, but a human being suffering from an infection with the tubercle bacillus.

V.

TUBERCULOSIS FROM A DENTIST'S VIEWPOINT.

BY GEORGE H. WRIGHT, D.M.D., BOSTON.

We have heard the viewpoint of the surgeons and general practitioners, and of course I hear the viewpoint of the nose and throat men every week. The viewpoint of the dentist I think is important in this study inasmuch as most of the children which are treated for cervical adenitis are found between the ages of two and fourteen years.

These drawings* show: (1) A temporary tooth whose roots partially absorbed are in apposition over the crown and mesio-distal side of a permanent tooth. (2) A permanent tooth being un-

developed as to its root, lying beneath this temporary tooth, is easily pressed from above in the process of mastication. (3) A permanent tooth, first molar erupting through the gums approximately at six years of age showing large pulpy mass of embryonic connective tissue showing blood vessels, non-medullated nerves and only partial development of its roots. These states of tooth development are normal and exist through infancy and childhood and up to the time of eruption of the third molars. A consensus of observations find cervical adenitis in humans between two and fourteen years.

There exists a definite anatomical relation between these teeth and cervical glands. As the upper teeth develop we have growth of the face from the floor of the orbit downward, at the same time the face expands laterally. The lower jaw grows backward in the direction of the angle and ramus of the jaw, and subsequently becomes the location for three permanent molars. This growth is influenced through the function of use in mastication and deglutition. In this normal physiological process of growth, bone is formed, absorbed and reformed. Hence the necessity for lymphoid glands, which care for normal physiological waste.

The glands involved in this process are definitely bounded and located within a small triangle anterior to the sterno-cleido mastoid. From the symphysis of the lower jaw at the median line down to upper border of the hyoid bone, then backward and obliquely upward to angle at ramus of jaw with the lower border of jaw as base we have a small triangular area into which drains all material physiological or pathological from the alae nares, the vestibule of the nose, lips, cheek muscles, tissues of the gum, ligaments around the teeth called the periodontal membranes, the alveolar process and the jaw bone. This does not include the faucial tonsillar gland, which lies near the anterior border of the sterno-cleido mastoid and is drainage for the tonsil. Having considered these two relations: (1) The mechanical factors of normal eruption with the pump-like action of the pressure of mastication. (2) The anatomical status of the teeth and structures involved in a glandular enlargement within a limited triangular area, we finally consider a third factor influencing the entrance of the tubercle bacilli.

I believe the individual or combined activities of the streptococcus, staphylococcus, or pneumococcus, and occasionally other microorganisms, are the common predisposing factors and almost necessary agents which prepare the tissues and open a pathway for the subsequent invasion of tubercle bacilli. Such agents we always find in a dirty and diseased condition of the teeth and adjacent structures. This belief is strengthened and confirmed by experimental researches and recent clinical observations.

Cornet (*Journal American Medical Association*, Aug. 6-13, 1910) demonstrated before the tenth meeting of the German Surgical Society

* See *Loc.* BOSTON MEDICAL AND SURGICAL JOURNAL, May 2, 1914.

that he could produce tuberculosis of the cervical glands by inoculating pulps of teeth through artificial cavities of animals. Then obtained the same results by rubbing cultures of the tubercle bacilli between the lower incisors, root and alveolar process.

Baumgarten (*Journal American Medical Association*, Aug. 6-13, 1910) fed animals on tuberculous material. In every case produced tuberculosis of cervical lymph glands and found an involvement coincidently of the tonsils.

Odenthal (*Journal American Medical Association*, Aug. 6, 1910) found in 131 cases of caries of the teeth a glandular enlargement on one side only and that associated with the teeth.

Reese tabulated 13,167 children, 80% with carious teeth.

Stark (*Britr. Z. Klei. Chir.*, xvi) examined children with cervical lymphadenites, 80% with carious teeth; 16% of the 80% with hereditary predisposition to tuberculosis, 41% of the 80% no other cause than carious teeth. Average age, eight and one-half years.

Morelli and Jaruntowski (*Zahnartzl. Wochenschr.*, viii, 3701) demonstrated tubercle bacilli in carious teeth of patients suffering from phthisis.

Hoppe found tubercle bacilli in carious teeth of otherwise healthy patients.

The possibilities bound up in the micro-organism streptococcus when it leaves one live body to continue its growth in another are enormous. This bacillus alone is capable of lowering the vitality of the tissues and through its hemolytic action on the blood and adjacent structures to render a pathway for the invasion of tubercle bacilli a simple matter, and although at times the streptococcus may be harmless it possesses the alarming capacity through transmutation of becoming a most virulent germ. As to whether it becomes harmful or not appears to depend on its environment and oxygen supply.

For example:—

An abscessed root of a tooth with a confined gangrenous pulp and necrotic area of alveolar process deep down below the surface of the gum, would favor the growth of the virulent type of pus-forming streptococcus through lack of oxygenation of the parts, whereas such micro-organisms might be recovered from the surface mucosa of the mouth, and on cultivation and inoculation show the harmless variety by comparison. It is a localized hemolysis that has prepared a favorable pathway for the subsequent invasion of the tubercle bacilli through the structures described, into lymph spaces not definitely defined by endothelial walls, thence into the true lymph vessels and finally into the cervical glands. I believe this is the mode of entrance for toxins into the system, as manifested in arthritis, when associated with infection from the teeth, albeit the local glands are not involved or enlarged.

A word relative to the discussion by Dr. Chad-

wick: We consider all tuberculous patients poorly equipped unless they are surgically clean as to teeth and alveolar process and decidedly handicapped when unable to properly prepare food for assimilation without teeth with which to masticate; if not by natural means then substitutes should be provided. We believe every institution for the treatment of tuberculous diseases should include a proper care of the teeth and mastication.

Summary.—We have shown the anatomical relation between teeth and glands. (2) A mechanical factor, influencing the pumping into the adjacent tissues of debris through loose teeth and mastication. (3) A prepared pathway and open door for the entrance to glands of tubercle bacilli by the localized hemolysis of tissues through the action of the streptococcus and other bacteria.

DISCUSSION.

A. N. BROUGHTON, M.D., Jamaica Plain, Mass.: Dr. Porter has stated, in a very large measure, what I believe about the subject under discussion. When I was at the hospital here we had the régime where nearly all the men did a complete dissection of the neck for tubercular adenitis. Those were the days in which we had extensive, mortifying, and disfiguring scars very commonly. When I got out of the hospital, I found it an imperative thing to clean up the neighborhood in which I lived of tonsils and adenoids. In the first ten years, I did a considerable number, thinking that all large tonsils and adenoids needed operation. The same thing applied to tubercular glands. In later years, not because I have cleaned up the neighborhood entirely, I have operated more and more sparingly on glands, tonsils, or adenoids.

My attention was called to the relation between the teeth and the tonsils by Dr. Wright's work, of which he will speak later. In a reprint of his and Dr. Cobb's, I got my first suggestions as to the relation between those structures. I have come to believe entirely in the theory that the enlargement of tonsils alone is not an indication for operation.

In the cases of cervical adenitis, I notice that most of the men who have spoken have grouped them very largely as tubercular, even if they were not demonstrable as such, and I agree that a large percentage of them are tubercular and of the bovine type, even when a tubercle cannot be pathologically demonstrated. I believe that the thing of the utmost importance to do first is to get rid of the focus. It seems to me foolish to operate on the glands of the neck and leave a source of infection in the throat. Having gotten rid of the tonsils or adenoids which are infected or the carious teeth, the next problem is a very considerable one, and I agree with Dr. Hawes, as well as Dr. Porter, in believing that in all cases a most thorough and comprehensive anti-tubercular treatment should be faithfully tried until it is perfectly clear that the glands will not quiet

down. If they do not, after an extended trial, I believe in operating. Even then, I think it wise to get out with as little disturbance of the glands as possible.

Judd's statistics, of which Dr. Porter spoke, are interesting. There is one paragraph in which Judd states that a very large number of glandular enlargements disappeared after they cleared up the tonsils and teeth, which were the sources of the enlargement, without coming to radical operation. This goes hand in hand with his statement that if you were to examine a very large number of children under fifteen, in a majority of cases you would find a distinct glandular enlargement. So that although Judd reports over 600 cases as operated, it is obvious that many more were not operated excepting to remove the tonsils or adenoids. In other words, apparently, they believe at Rochester that the thing of first importance is to remove the source of the infection, and that a large portion of the glands will quiet down of themselves after that.

I want to call attention to the statement of Dr. Richards in relation to operating on children for tonsils and adenoids, where the parents have been tubercular. It seems to me it would be a mistake to do that commonly. You cannot get away from the fact that if you take away a healthy tonsil, you are removing one line of defence. When those defences have lost their value, it is right and proper to remove them. But to anticipate and operate on an otherwise healthy tonsil merely because the parents have been tubercular seems to me far too radical. It goes without saying, that at the first sign of infection, they should be operated.

I think there is a distinct choice as to the right time for operating even on the tonsils and adenoids. Where the glands are enlarged and are about ready to break down, by operating one throws an additional burden upon the glands and increases the amount of septic absorption and hastens their breaking down. If possible, I like to do a tonsillectomy when the glands are receding, or before they are at all near the breaking down point. Again, in these cases I would emphasize the need of a faithful anti-tubercular treatment before deciding that it is necessary to operate. In this respect, many of the good results of Dr. Chadwick's cases, I believe, were not alone due to the use of tuberculin, which he emphasized, but also to another advantage, which he did not speak of, the very efficient anti-tubercular treatment that they had in other respects. My experience with tuberculin has been smaller than any hospital practice would give, but I think it is one of the agents which in carefully selected cases very materially helps.

As to mortality in a radical operation, I do not think that ought to weigh in the scale, materially. There should be, roughly speaking, little or no mortality. I doubt if it is a question of that nearly so much as a question of scar and

the dread, not of recurrence, but the growing of smaller glands which were overlooked. I do not care how careful the dissection is, it is surprising how many small glands will be found to be somewhat enlarged, even shortly after the operation. Those glands were simply overlooked at the time of operation.

The cases of tubercular adenitis that are under two years of age I believe to be more serious than in older children. It is much harder to take care of them by any anti-tuberculous treatment in my experience, and I consider them very grave cases for prognosis.

D. CROSBY GREENE, M.D., Boston: I was interested in seeing the drawings of Professor Most, because there is an article which he published five or six years ago which is of some moment as bearing upon the discussion this afternoon. He at that time made a series of injections to determine the foci of infection of cervical tuberculous glands. He published the results of these injections, which were somewhat as follows: A large majority of the afferent lymph channels of these glands were traced somewhere in the tonsillar region, the region of the pharyngeal tonsils. The proportion was about 70%. A surprisingly large proportion, 13% as I recall it, was found to derive its infection from sources which were near the surface of the skin. These places were the point of juncture between the skin and mucous membrane at the corners of the mouth, at the entrance into the nose and at the margin of the eyelids. In about 13% of the cases, which numbered over 100, the infection was traced to these superficial places on the face. The remainder of the cases apparently were infected from the teeth and other places inside the mouth.

Dr. Porter has said that it is up to the throat men to arrive at some unanimity as to whether a tonsil is the source of infection or not in a given case; that in a given case we should learn whether a tonsil is tuberculous or not. This is a very difficult proposition. We know in the first place that the presumption is in favor of the tonsil as the portal of entrance for infection. We know also that in a very large proportion of tonsils in cases of tuberculous adenitis it is impossible to find evidence of tuberculosis either by microscopical examination or by bacteriological examination or by injection. In my own experience (I have not tabulated the cases) I have had examinations made in a great number of cases and the results have not been at all definite. In some cases of tuberculous adenitis, tubercle bacilli have not been found in the tonsils. In some cases we very often got no evidence of tuberculosis in the tonsils. In other words, the tubercle bacilli can make their way through a tonsil into the gland without leaving any trace in the tonsil itself in the way of tuberculous disease of the tonsil or even without the presence of the bacillus of tuberculosis. There are, of course, cases in which it is possible to make the diagnosis of tuberculosis of the tonsils, but I be-

lieve such cases are extremely rare. Cases in which a distinct lesion, which can be classified as being a tuberculous lesion of the tonsil, are so rare as to be negligible. I have not seen more than two in my experience. I believe they must be very rare. These are usually cases of tuberculous ulceration of the tonsil, which do not constitute any considerable portion of the cases under consideration.

JAMES S. STONE, M.D., Boston: It is important to recognize that by no means all glandular swellings in the neck are tuberculous. Comparatively few of the sudden, acute, painful swellings are of this character. The location of the swollen glands gives some indication of the nature of the infection. In determining the primary focus from which the cervical glands become infected, certain anatomical points are of great help. If a line is drawn vertically upward from the middle of the auditory canal, roughly speaking any infection in front of that line and above the outer corner of the eye may lead to involvement of the preauricular glands; any infection on the face below the outer corner of the eye but above the outer corner of the mouth may involve the glands which are in front of the angle of the jaw close to the groove in which the facial artery can be felt; any infection below the corners of the mouth may involve the submental glands; any infection behind the line drawn upward from the middle of the auditory canal drains back into the posterior group of glands. These simple guides, though not strictly correct anatomically, serve as a good clinical working basis. The lymphatics of the throat, the nasopharynx and the tonsils, drain into the deep glands which lie behind the angle of the jaw and under the middle of the sterno-mastoid muscle. The lymphoid tissue of the naso-pharynx is without question the most common point of entry or seat of primary infection in cases of tuberculous cervical adenitis. But neither the gross appearance of the tonsils nor the clinical manifestations of adenoid hypertrophy bear any constant relation to the severity of the infection of the cervical lymphatics. The lymphatics from the tonsils pass a little further forward, nearer the anterior edge of the sterno-mastoid muscle, than do those from the posterior pharyngeal wall or the Eustachian tube, which may lead into glands near the posterior border of the sterno-mastoid muscle. The glands involved in infections of the middle ear usually lie behind the sterno-mastoid.

These definite anatomical groups of glands give us a clue as to the source of the infection. Cervical adenitis is always a secondary infection. There must be some point of entry from which the infection starts. This point of entry is not always evident when we see the enlarged glands. The original source of infection may be healed. Moreover, a relatively normal tonsil may allow the passage of tubercle bacilli through it and

not itself become infected. It is sometimes impossible to tell whether a tonsil is or is not infected. If the tonsillar group of glands is infected, even though no primary source of infection can be found, it must be assumed that the tonsil is not normal and ought to be removed, even though it shows no sign of disease; because the evidence is practically overwhelming that it has been the point of entry and may still contain the focus of infection.

No mention has been made of something which frequently occurs after complete enucleation of the tonsils. I refer to the development of lymphoid tissue along the posterior pillars of the fauces. Since complete enucleation of the tonsils has become common, we are, I think, beginning to see more and more retro-pharyngeal adenitis. Frequently I have seen lymph nodes, and have at times dissected out tuberculous lymph nodes, at the point of the posterior pharyngeal wall which comes in view as you look in underneath the soft palate. Within the last few months I have seen more such cases of lymph node infection in that region than before. I think this is in part due to the development of the lymphoid tissue, which seems to take the place of the enucleated tonsils. This reformation of lymphoid tissue should make us conservative and not allow us to yield without reason to what is becoming a common request of parents, that the tonsils and adenoids be removed because a child has occasional or even frequent colds.

In addition to recognizing that lymphadenitis is a secondary infection, and recognizing the importance of removing the primary focus, we must remember that hygienic treatment is of supreme importance both before and after operation. In that I would agree absolutely with Dr. Hawes. Dr. Chadwick mentioned the importance of sanatorium treatment, making the very suggestive statement that the cases in which he had failed with tuberculin were out-patients at his sanatorium, where he could not give them the out-door hygienic care.

Dr. Porter spoke of three groups of cases. The first included babies under two years of age. I feel very strongly that these are among the most serious cases with which we have to deal. A child under two years who develops tuberculosis has little resisting power, or a very serious infection, is a poor risk. They have no business to develop tuberculosis at that age. If they develop it, whether they are treated medically or surgically the risk is great. In each individual case the treatment must be outlined according to circumstances. If the only important focus is in the cervical glands, that ought to be treated surgically. If the cervical adenitis is only part of a general tuberculosis, then surgical treatment is a minor consideration.

The second group mentioned by Dr. Porter included the cases coming on in older children. He mentioned the difference between the cases

of lymphadenitis in children and the cases which occur in adults. I think that there is a very definite basis for the difference. In children the vast majority of the cases of lymphadenitis occur in the tonsillar group right under the middle of the sterno-mastoid muscle. I feel that the bulk of those cases are of the bovine type, and that the liberal milk diet of children is a great etiological factor in those cases—a bovine infection, tuberculous milk, the bacilli entering through the tonsils and spreading to the glands.

In the third group, including adults, the cases resemble somewhat those seen in babies. The infection is more frequently of the human type, and often the lymphadenitis is only a part of a general tuberculosis. The source may not be directly from the tonsils; it may not be directly from the lungs. These patients have a lowered resistance to the tubercle bacillus. The infection may involve chiefly lymph glands, or may involve any organs of the body. In those cases where the infection spreads from one group of lymph glands to another the fact that any particular glands are affected does not mean that the source is in the region from which the lymphatics enter the particular glands, but that there is a systemic infection, the involvement of the lymph glands being an incident.

Dr. Hawes says he holds no brief for tuberculin. I hold no brief against tuberculin. Many swollen glands subside while being treated with tuberculin, as they do under other methods of treatment. The much despised poultice used to be a favorite treatment. A flaxseed poultice will do one of two things. It will either, if it is possible to bring about resolution, hasten this, or if the disease is so advanced that this is impossible it will hasten breaking down. It will make the glandular condition declare itself. It will clear up a condition in the same way that Dr. Hawes says tuberculin clears it up. These are the cases where good surgical judgment is necessary. If one objects to the term poulticing as being old-fashioned, it may be called inducing hyperaemia.

Cases of tuberculous lymphadenitis should be treated either as glands or as abscesses. I feel more and more that no middle ground is tenable. We ought to excise glands or open and treat abscesses. If enlarged glands have persisted for a material length of time and are not subsiding within a couple of months, then those glands ought to be removed surgically, provided there are not complications which render this unwise. If the adenitis is only a complication of a medical tuberculosis then we must treat each individual case on its merits.

In children the removal of the glands and of the primary trouble in the vast majority of cases cures the infection once and for all. The cause must be removed. If we cannot treat the glands as glands and remove them, then they should be treated as abscesses. A question is very com-

monly asked by parents and by patients today; one put in their mouths by the medical men of an earlier generation. "Is it ready to open?" That question is most pertinent. The best results in treating abscesses can be obtained by letting the glands thoroughly soften down, become thoroughly walled off, not by a firm fibrous capsule, but by a zone of inflammatory tissue. Let the abscess come near to the skin, but not involve the skin, for skin involvement means slow healing and disfiguring scars. Then when the glands have formed an abscess it can be drained, the tuberculous material can be thoroughly removed by curetting and wiping out with gauze. The best results can be obtained by a thorough, careful, painstaking cleaning out of the abscess cavity, followed by packing lightly but thoroughly into every recess of the cavity with gauze. The gauze may be left untouched for a period of four or five days, or even a week. It may smell bad, it becomes saturated with pus, but during this time there has been opportunity for the inflammatory wall around the outside to throw out granulation tissue. The wick at the end of five or six days may be removed and nothing replaced. Very frequently an abscess so treated will heal immediately and give no further trouble. In this way the constant dressings, which to children especially are terribly trying, with the frequent packings, cauterizations, and the long drawn out treatment of sinuses, may be avoided.

The cases in which some glands are only just becoming caseous, while others have been completely destroyed and formed abscesses, are those in which the skilled judgment of the surgeon is necessary if a satisfactory outcome is to be obtained. Fortunately we see today in the hospitals much less severe cases than were formerly common. Patients seek treatment earlier.

One thing in regard to the scars is important. A line of incision along the skin fold of the neck gives a trifling scar. But if the incision is long it is absolutely essential that the platysma which lies at right angles to the line of the skin folds of the neck should be stitched, because if this is not stitched then the line of the scar inevitably spreads.

It is most important to visualize as clearly as possible the entire pathological process. If the complications or the general health of the patient are the chief factor the treatment of the glands themselves becomes a matter of comparatively little significance. When, however, the glands are the chief manifestation of the tuberculous process, one should picture clearly exactly the condition of the glands. When the infection first begins there is swelling due to congestion and edema. This at first is confined to the glandular structure alone, but if the process is severe it very soon spreads into the peri-glandular tissues. The spread into the peri-glandular tissue is what brings on pain on movement and the ordinary symptoms of a stiff neck. There

may be hyperemia and swelling of the glands and also peri-glandular inflammation without the process going on to caseation. If, however, the process continues long, a caseous destruction in the central portion of the gland is inevitable. This may occur in one or in many foci within the glands, but for a long time there may be a considerable amount of glandular tissue left intact.

Sometimes before the destruction of the glandular tissue has become complete, the disease may spread through the capsule into the surrounding tissues. In other cases where the process is more slow the destruction of the gland goes on so quietly that the process is entirely confined within the capsule. The spread of the caseous process into the peri-glandular tissues renders the formation of an abscess certain. This process spreads in the soft parts until it reaches the skin, then it involves the skin, finally perforates the skin, and a fistula becomes established, which may or may not heal, according to the resistance of the patient and the particular conditions existing in the course of the fistula. If the caseous process is confined within the capsule of the gland, then for an indefinite time, even for many years, there may remain a tuberculous cyst in which the organisms may be dead—or at least are absolutely quiescent—until something in the general condition of the patient or some local trauma lights up the process again.

With a mental picture of the pathological process clearly in mind, the surgeon should decide whether he can aid nature by eradicating the disease or whether he can better and more safely aid nature by simply hastening a destructive process which ordinarily is slow and tedious; but the surgeon should have an opportunity to decide sufficiently early to be given a choice.

VISCERAL PTOSIS. A REVIEW.*

By JOHN T. WILLIAMS, M.D., BOSTON,

Fellow in Gynecology, Harvard Medical School; Third Assistant Visiting Surgeon for Diseases of Women, Boston City Hospital; Assistant to the Surgeons, Gynecological Department, Boston Dispensary.

THE subject of visceral ptosis is exceedingly complicated, ptosis being not a local process, involving one or a few organs, but part of a much more general condition, involving not only the abdominal contents, but the musculature and bony framework of the body as well.

Although the clinical picture of enteroptosis was clearly described by Glenard¹ in 1885, fail-

ure to recognize the general nature of the condition has been responsible for almost uniform failure of all methods of treatment. The work of recent writers, especially Goldthwait,² Martin,³ Smith,⁴ and Coffey,⁵ has resulted, however, in a clearer understanding of the subject.

It is my purpose to review briefly our present knowledge of the mechanics, causes and symptoms of visceral ptosis and to set forth with a little more detail the varying ideas as to its treatment.

Clinical Appearances. The clinical appearances are easily recognized by the characteristic ptotic figure. The attitude is that of physical weakness. The individual is round-shouldered and flat-chested, standing with the head drooping and arms hanging in front of the center of gravity of the trunk. The waist line is high, the lower abdomen protuberant, giving in uncorseted women not infrequently the appearance of pregnancy. The costo-vertebral angle is more acute than normal. The lumbar curve of the spine is usually obliterated, giving rise to the straight back, although occasionally the lumbar curve is exaggerated to the point of lordosis. The muscular development is below par and the patient is usually thin and anemic.

Closer observation shows that the abdominal cavity is narrower above than below, because of the flattened chest and straight spine. The pelvic inclination is much diminished, the sacrum being perpendicular and the lower border of the symphysis pubis sometimes at a higher level than the coccyx. As a result of this, the axis of the pelvis is continuous with that of the abdomen, instead of forming an angle with it, as normally.

Gynecological lesions are rather common, not as a direct result of the prolapse of the abdominal viscera but of the patient's general lack of tone.

Anatomy. In order to fully understand the anatomical conditions present in ptosis, it is necessary to review the differences in development between man and the quadruped. In the quadruped, it will be remembered, all the intra-peritoneal viscera are freely movable and equipped with a mesentery.

In man, on the other hand, certain changes in development take place in order to furnish additional support to the abdominal organs, necessitated by the erect posture. Briefly stated these are:

1. Fusion of the liver with the diaphragm.
2. Retro-peritoneal fixation of the duodenum and pancreas by obliteration of their mesentery.
3. Adhesion of the ascending and descending colon and mesocolon to the posterior parietal peritoneum.
4. Adhesion of the transverse colon to the great omentum.
5. Fusion of the anterior and posterior layers of the great omentum.

The separate means of support of the individ-

* Read before the Chirurgical Society of Boston, Sept. 17, 1914.

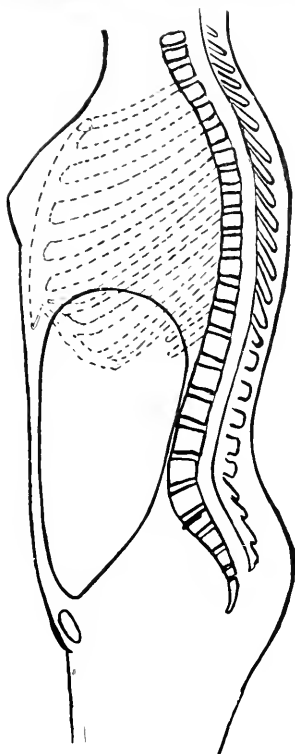

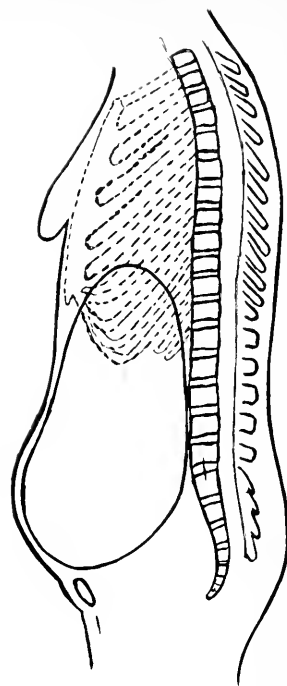

FIG. 1.

FIGS. 1 AND 2.

FIG. 2.

Showing the differences between the normal figure (1) and the prototic figure (2). In the latter, note the protuberance of the abdomen; its greater width below than above; the absence of an angle between abdominal and pelvic cavities; the diminished pelvic inclination; the straight spine; flat chest; and the more acute costo-vertebral angle.

ual organs are as follows: The posterior half of the liver is fused with the diaphragm, the ventral half being supported by the falciform ligament. The cardiac end of the stomach is firmly fixed by the esophagus and gastro-phrenic ligaments. The remainder of the organ is suspended from the under surface of the liver by the lesser omentum, which is thickest at its free border, where it contains the vessels going to the liver and the bile ducts. The pancreas and duodenum are retroperitoneal and firmly attached to the vessels in front of the vertebral column.

The duodeno-jejunal angle is supported by the muscle of Treitz, which runs to the left crus of the diaphragm. The small intestine is freely movable, being attached to the posterior abdominal wall by its mesentery, which is shortest near the termination of the ileum. The cecum and ascending colon are adherent to the posterior abdominal wall, their mesentery having become fused with the posterior parietal peritoneum. The hepatic flexure receives support from the liver by the hepato-colic ligament. According to Longyear, it is also connected with the right kidney by a firm band of fibres, but this offers no support to the colon because the right kidney is the least firmly supported of all the abdominal organs.

The transverse colon is suspended from the stomach by the gastro-colic omentum and indi-

rectly from the diaphragm through the liver, lesser omentum and stomach. The splenic flexure is the most firmly supported point of all, being held in position by the gastro-colic and gastro-splenic ligaments. The descending colon is also firmly attached to the posterior abdominal wall by fusion of its mesentery with the posterior parietal peritoneum. The sigmoid has a short mesentery.

The kidneys are retroperitoneal, surrounded by a fatty capsule, and undoubtedly derive more or less support from the parietal peritoneum and the layers of the fused mesentery of the ascending and descending colon.

In addition to these direct supports which we have described, there are two important factors in maintaining certain of the abdominal organs in place. The first of these, the backward pressure of the abdominal wall, is sufficiently obvious.

The second was pointed out by R. C. Coffey.⁵ If we look at a sagittal section of the normal body (Fig. 3), we observe that the kidneys are situated in the lumbar fossae, behind the peritoneum, and back of the line of downward pressure on a sort of shelf formed by the lumbar curve of the vertebral column and the psoas muscle. This shelf makes an angle of 51° with the horizon and undoubtedly plays no small part in the retention of the kidneys in normal position.

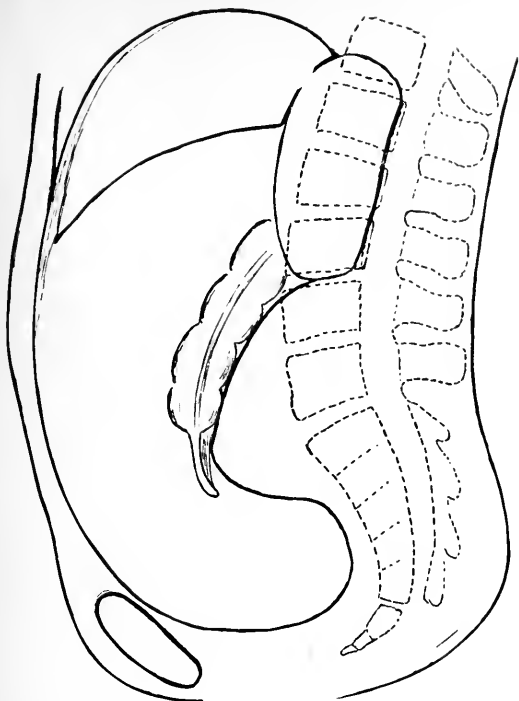

FIG. 3.

Showing the kidney shelf formed by the psoas magnus muscle with the lumbar curve of the spine.

Goldthwait lays considerable stress on the importance of the cervical fascia, which through its continuation, the pericardium, forms a suspensory ligament for the diaphragm. He has demonstrated that putting the cervical fascia on the stretch by throwing the head backward will raise the stomach three to four inches.

The most firmly supported points in the visceral tract are the cardiac end of the stomach, the splenic flexure of the colon, the pylorus and the duodenum. The least firmly supported points are the stomach between its two extremities, the cecum, ascending colon, hepatic flexure and transverse colon. For this reason prolapse of the right kidney occurs early in the process; and is extremely common. Prolapse of the left kidney, on the other hand, is found only when the splenic flexure, the most firmly supported point of the intestinal tract, gives way, and is indicative of the most complete form of ptosis.

Looking at the support of the abdominal viscera from a slightly different point of view, we see the cervical fascia, attached above to the base of the skull, continued downward as the pericardium, giving support to the dome of the diaphragm. From the diaphragm is suspended the stomach by means of the liver and lesser omentum; and from the stomach, the transverse colon by means of the great omentum. In the round-shouldered stooping attitude there is lack of tension on the cervical fascia, dropping of the dome of the diaphragm, and therefore prolapse of the stomach and transverse colon, aided, of course, by the relaxed abdominal muscles, flabbi-

ness of the omentum and atony of the muscles involved. This constitutes mid-line ptosis.

The support of the right kidney is intimately associated with that of the hepatic flexure of the colon, as we have seen, and therefore prolapse of the kidney is always associated with ptosis of the hepatic flexure and ascending colon and cecum mobile. This constitutes right-sided ptosis. These two forms of ptosis may be associated or occur separately.

Two conditions must be mentioned which are frequently associated with visceral ptosis, namely, Lane's⁶ kink and Jackson's⁷ membrane. There is wide variation of opinion as to whether these are directly concerned with the ptosis or are merely coincidences.

Lane⁶ himself considers the ileal kink the result of ptosis of the cecum, with the resulting crystallization of the lines of strain into peritoneal adhesions. Coffey,⁵ on the other hand, believes Lane's kink to be due to chronic inflammation not associated with ptosis.

Regarding the etiology of Jackson's membrane, there is again divergence of opinion. Jackson⁷ supposed the condition due to infection from within the cecum. Mayo^{8a} believes this membrane formation to be the result of late rotation of the colon, and descent of the cecum from its hepatic position after formation of the posterior parietal peritoneum. In this event the cecum burrows its way into its position in the right iliac fossa, investing itself with an extra layer of peritoneum, which ultimately becomes the pericecal membrane. Lane⁶ ascribes the pericecal membrane to the same causes as the ileal kink, namely, the development of peritoneal adhesions to resist the prolapse of the cecum.

Etiology. The causes of ptosis generally agreed upon are:—

1. Defects in development.
2. Faulty attitude.
3. Deficient musculature.
4. Rapid loss of flesh.
5. Repeated pregnancies.

It is probable that none of these causes alone is ever responsible for prolapse of any of the viscera. Certain individuals seem to be predisposed to ptosis by hereditary peculiarities of physique or congenital defects in development. The flat chest and straight spine may be inherited. Among the congenital defects in development which have been noted are:—

1. Failure of the colon to rotate completely into the right flank and carry its mesocolon across the front of the right kidney, depriving that organ of one of its most important means of support.
2. Failure of complete fusion between the right meso-colon and the posterior parietal peritoneum, resulting in cecum mobile.⁹ This occurs in 20% of all individuals.
3. Failure of the layers of the great omentum to fuse, allowing prolapse of the transverse colon.

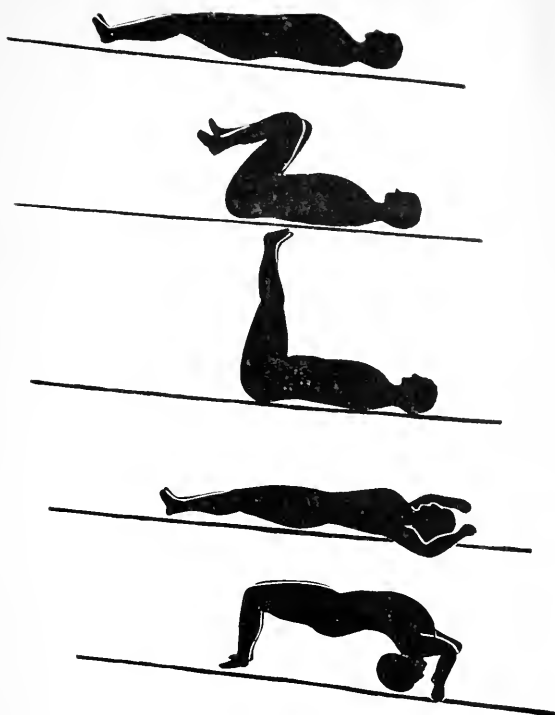

FIG. 4.

FIGS. 4 AND 5.

MARTIN'S EXERCISES.

All of these with the lower extremities require the fixing of the pelvis upon the trunk which is done by the muscles of the abdominal wall.

The first figure shows the position of the patient ready to begin the exercises.

Exercise 1. Flexion of the thigh upon the abdomen and the knees upon the thighs, brings into play, in addition to the muscles of the abdominal wall, the quadriceps extensor, hamstrings and iliopsoas.

Exercise 2. Flexion of the thighs with the legs extended brings into action the abdominal muscles, the iliopsoas and quadriceps extensor.

Exercise 3. Forced inspiration and expiration with the arms above the head. This brings into use the abdominal muscles as muscles of respiration, but particularly exercises the diaphragm, intercostals, pectorals, sternomastoid, trapezius and deltoid, as well

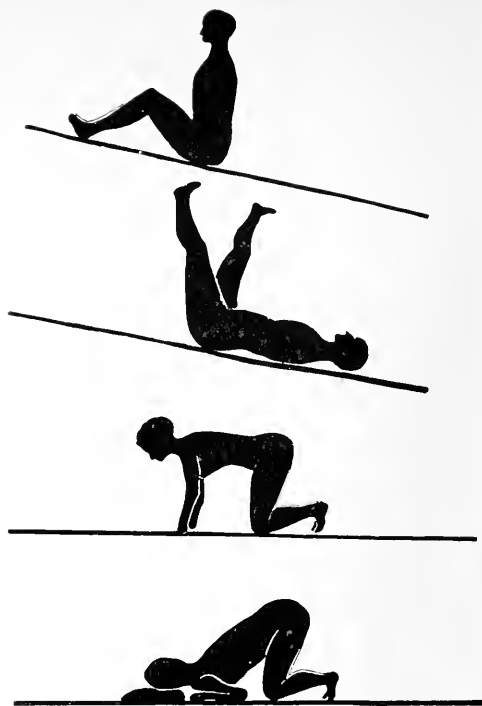

FIG. 5.

as the muscles of the arm. Martin considers this the most important of all the exercises, and alternates it with each of the other exercises.

Exercise 4. Raising the trunk upon the heels and hands develops nearly every muscle in the body, but especially the muscles of the back and upper and lower extremities.

Exercise 5. Raising trunk to sitting posture. This brings into play all the abdominal muscles, but chiefly the rectus.

Exercise 6. Adduction and abduction of the lower extremities, the thigh being flexed on the abdomen and the legs extended. This requires the use of all the abdominal muscles to fix the pelvis upon the trunk, but especially exercises the adductors, the obturators and pyramiformis, and of course the quadriceps extensor and iliopsoas.

Exercise 7. Inspiration and expiration on the hands and knees.

Exercise 8. Inspiration and expiration in the knee-chest position.

These two exercises are designed for women with retroverted uteri, the position and upward movement of the diaphragm tending to draw the uterus into normal position.

When in an individual predisposed by defective development, deficient musculature and faulty attitude occur, ptosis is inevitable. Rapid loss of flesh and repeated pregnancies exaggerate the condition.

Symptomatology. The symptoms of visceral ptosis may be divided into three groups:—

1. Gastric and intestinal stasis.
2. Pain due to tension on mesentery and peritoneum.
3. Neurasthenia.

Of the symptoms due to stasis, obstinate and prolonged constipation is the most pronounced. After this come gas formation in stomach and intestines, gastric distress, loss of flesh and strength, lowered muscular tone, and staining of the skin. The prolapsed stomach presses on the pancreas and interferes with its secretion, explaining many of the gastro-intestinal symptoms. The type of chest and the general malnutrition render this class of individual more susceptible to pulmonary tuberculosis and other infections.

Goldthwait^{2b} has suggested that infectious arthritis may be due to absorption of toxins from the small intestine, the absence of pancreatic juice, which exerts an antiseptic action, allowing increase in bacterial growth.

The pain in visceral ptosis, aside from that due to disturbed digestion, is usually referred to the region of the umbilicus or lower abdomen, with the exception of that caused by movable kidney.

Of the neurasthenic symptoms it is hardly necessary to speak. In the most advanced cases they may be referred to every organ of the body.

Diagnosis. The diagnosis presents no difficulty, the characteristic enteroptotic figure being easily recognized. The x-ray and bismuth meal offer an exact method of determination of the degree of ptosis and stasis.

Treatment. Treatment may be considered under four heads: Medical, Gymnastic, Mechanical, Surgical.

Medical treatment should be directed to the improvement of the general condition, especially by proper diet, and to the relief of individual

symptoms, especially that of constipation. For the relief of this symptom nothing is so efficacious as the lubrication of the intestinal tract with liberal doses of the mineral oil known under the names of "liquid paraffine," "Russian oil," etc.

Gymnastic treatment may be said to include posture, exercises, and massage. The most careful attention should be paid to posture, correcting the drooping shoulders, the forward bend of the spine, and the protuberance of the abdomen. This is equally as necessary while sitting and lying as while standing. The patient should sleep without a pillow on a fairly hard bed; the effect of a pillow being to push the head forward, contracting the upper part of the chest, and relaxing the cervical fascia. The use of the Trendelenburg position is of value at times in the temporary relief of symptoms due to the stasis.

Of the mechanical methods of treatment, the corset is the most valuable. A good corset should have the following characteristics:

1. It should be short behind, especially at the top.
2. It should be long in front, especially at the bottom.
3. It should fit tightly about the pelvis.
4. It should fit loosely at its upper extremity.
5. It should lace in front.

Such a corset will throw the center of gravity backward, as shown by Reynolds and Lovett.¹⁰ The proper application of the corset is of the utmost importance. It should be applied in the recumbent, or, better, Trendelenburg, position. It should lace in three sections, the lowest one very tightly, the middle less tightly, and the upper should produce no pressure whatever.

The various appliances for the relief of floating kidney have been universally unsuccessful because they have been designed without regard to the ptosis, of which the kidney is only a part. A well-fitting corset, by producing backward and upward pressure on all the viscera, will give better results than any of the special apparatuses for floating kidney.

Surgical Treatment. The great difficulty with the surgical treatment of ptosis is the multiplicity of conditions to be rectified. Coffey⁵ gives the following list of operations which may be indicated.

Operation for Lane kink.

Operation for cecum mobile.

Operation for movable kidney.

Coffey's operation on great omentum.

Beyea's operation on lesser omentum.

Shortening of falciform ligament of liver.

Operations for changing shape of abdomen.

(a) On lower abdomen. (b) On upper abdomen.

To these may be added removal of Jackson's membrane, appendectomy, operations on the female pelvic organs and perineorrhaphy. Concerning the operations of Kellogg¹¹ and Martin¹²

on the ileo-cecal valve, we can only say that they are too experimental for discussion at present.

Operation for Lane kink as performed by Coffey⁵ consists in division of the constricting band and shortening of the upper leaf of the mesentery.

There are a number of operations designed for cecum mobile. Wilms⁹ splits the peritoneum in the right flank and then buries the ascending colon, making it retroperitoneal. Coffey⁵ and others simply suture the cecum to the posterior parietal peritoneum at the proper level.

Where Jackson's membrane is present, removal of the membrane, especially at the constricting portions, is the operation most universally done, although Connell¹³ twists the membrane into a rope, which he passes through the peritoneum at the outer side of the colon, and after drawing it through the muscle sutures it to the aponeurosis, forming a suspensory ligament for the cecum.

Of the operations for movable kidney it seems hardly necessary to speak.

Coffey⁵ has devised an operation for shortening the falciform ligament of the liver by a series of purse-string sutures. He also sutures the liver itself to the peritoneum by sutures passing through the liver on either side of the notch made by the termination of the umbilical fissure.

Beyea¹⁴ plicates the lesser omentum by a series of purse-string sutures.

Coffey suspends the great omentum, and by it the stomach and transverse colon to the anterior abdominal wall, by a series of sutures passing first through the peritoneum, near the original point of entrance. This line of sutures, usually about eight in number, runs transversely across the abdominal wall, being placed at such a level as to raise both the stomach and the transverse colon above the umbilicus.

In addition to these Coffey⁵ has devised two very ingenious operations for restoring the respective proportions of the upper and lower abdomen. The operation on the lower abdomen is as follows: An incision is made through the aponeurosis of the external oblique parallel to its fibres, and two to three inches above Poupart's ligament. The aponeurosis is separated from the underlying muscle for a distance of three inches above the incision, and then the upper part is overlapped over the lower and held by a row of mattress sutures. The same operation is performed on the opposite side. The diameter of the lower abdomen is considerably reduced by this operation.

The technic of Coffey's operation for expanding the upper abdomen is as follows: The abdomen having been opened by a high median incision to perform the various plication and suspension operations previously described, the peritoneum is closed as usual. Instead of uniting the fascia along the line of incision, however, the anterior rectus sheath is split one inch or more outside, and an aponeurotic flap dissected

up and reflected toward the median line, the reflected edges being brought together instead of the edges of the original incision, thus giving a considerable increase in the circumference of the abdomen. The denuded anterior surface of the rectus is not covered in except by the subcutaneous fat and skin, which are united in the usual manner, sometimes a small drain being inserted down to the fascia.

Lane^{6a} in cases of marked ileal stasis removes the entire large intestine except the rectum, uniting the ileum to the rectum by lateral anastomosis, thus getting rid of the stasis with its resulting auto-intoxication. The reader will be well repaid by a perusal of some of his papers, references to a few of which are given below.

Operative Results. Opinions differ widely. Coffey⁵ reports 41 cases treated surgically by various combinations of the procedures mentioned. Of these, 26 were symptomatically cured, 9 much improved, 4 somewhat improved, 1 unimproved, 1 died.

Rovsing¹⁵ sewed the stomach itself to the abdominal wall in 75 cases, in 22 of which he suspended the liver also, with good results.

J. G. Clark¹⁶ reports 55% of successes after the Coffey operation.

On the other hand, W. J. Mayo^{8b} says that "only a small number should be treated surgically. These patients are embryologically wrong."

Reynolds¹⁷: "Operation should be undertaken only when the surgeon has convinced himself that the local lesion is the cause of the symptoms and that the symptoms will be relieved by the operation."

R. R. Smith^{4a} performed various pelvic operations on 51 cases suffering from enteroptosis, of whom 15 were entirely relieved, and all but two received some benefit, although 19 were not relieved nervously.

Ochsner¹⁸: "I consider enteroptosis of small surgical importance."

Joseph A. Blake¹⁹ says: "There are two classes of cases:—

"1. Those in which ptosis of an organ contributes to the neurasthenic state simply by the effect on the organ itself (kidney, uterus, stomach). In this class the result of an operation depends on the degree to which the condition provokes or affects the neurasthenic state.

"2. Those in which a vicious circle is established (general splanchnoptosis). Operation in this class must relieve the auto-intoxication; and excision or exclusion of the colon is the only rational procedure."

Conclusion. The conflicting evidence reviewed in this paper is proof that none of the various methods of treatment has proved universally satisfactory. It is fair to say, however, that but few men have carried out any of the outlined procedures with the vigor ordinarily applied to the treatment of other pathological conditions. Concerning the surgical treatment, the amount

of work so far done is too small upon which to base an opinion. The number of surgical procedures which a single case demands must prohibit operative treatment in a considerable proportion of cases. Gymnastic treatment must be of great benefit early in the process, but unfortunately the anatomical changes are so extensive in advanced cases that but little help can be expected from exercises.

Corsets, although of course only palliative, and never quite relieving the patient's symptoms, nevertheless are of much value, and probably in advanced visceral ptosis will continue to give more comfort than anything else.

The greatest prospect for improvement lies in prophylaxis, as pointed out by Goldthwait. Certain individuals are predisposed to ptosis by anatomical peculiarities. These patients should be easily recognized by their tendency to the ptotic figures, and by general muscular insufficiency. Such persons taken early in life, their attitude corrected, and their muscles developed by exercise and proper food, it should be possible to prevent the development of extreme cases of visceral ptosis.

A FEW NOTES ON THE TREATMENT OF ANTEPOSED UTERI.*

By HENRY T. HUTCHINS, M.D., BOSTON.

THE mass of literature relative to malpositions of the uterus is enormous. Has there ever existed a surgeon, interested in gynecology, who has not at some time or other written his share and perhaps more than his share, on this subject? Several years ago I resolved that whatever I might write relative to any gynecological subject, the discussion of uterine malpositions was a completed chapter and I would never burden my hearers with additional theories in this field, but I have become thoroughly convinced that a large class of sufferers, the cause of whose

* Read before the Obstetrical Society of Boston, Oct. 27, 1914.

symptoms has previously passed by unrecognized, can be relieved by surgical means.

For many years we have regarded an anteposed fundus as the normal position of the uterus, and a uterus found in this position as incapable of producing pelvic symptoms, especially those of low sacral backache, pelvic drag and pelvic congestion. That the classical symptoms of retroposition of the fundus not only can, but frequently are, caused by a uterus in anteposition, I believe to be true.

In the diagnosis of the cause of low backache and the common symptoms of pelvic drag and discomfort, the gynecological and orthopedic surgeons ought more frequently to work together. A great deal is being written at present on the symptomatology and treatment of various degrees of ptosis of the abdominal organs, chiefly in the female patient. In this discussion, one organ, the uterus, has received but scant attention from the point of the clinical diagnosis from existing symptoms. The retroposed uterus is commonly accepted as a definite cause of backache and pelvic drag. The anteposed uterus is as universally regarded as incapable of producing these symptoms, and when the fundus is found to be in the forward position another cause for the patient's symptoms is usually sought.

Various degrees of retroposition are spoken of as "a uterus in first, second, or third degree of retroposition." The anteposed uterus has received but little attention from a symptomatic standpoint. My attention was called to this fact by the appearance of many patients in my clinic complaining of low sacral backache and feelings of lack of low abdominal support, pelvic drag, etc., in whom on examination the fundus was found to be anteposed. At first I was at a loss to explain these symptoms, which occurred as frequently in women who had not borne children as in those who had. This led to a study of the anteposed uterus in all cases, both when seen at the time of examination and also during the course of many abdominal operations for pelvic diseases. It was soon seen that the anteposed uterus was capable of as wide excursions from the normal as the retroposed. So many cases appeared with retroposed fundus who had no symptoms of backache and pelvic drag, that I came to disregard the position of the fundus entirely in making my diagnosis and began to confine my attention to the relative position of the cervix only, in relation to the pelvic frame. It was then found that anteposed uteri did not occupy a fixed position in relation to the pelvis, but they were found to be in varying degrees of ascensus and descensus, according to the stability of the cervical supports. Some were found to be held snugly up to the symphysis with the bladder and anterior vaginal wall well supported, while others were found to have dropped back toward the hollow of the sacrum, while still maintaining their anteposed positions. In considering these

cases, I refer only to those cases of descensus in an antero-posterior direction, and not those of beginning prolapse with rotation toward the pelvic outlet, which cases form quite another and distinct class.

On further investigation, it was found that in every case of what I have termed an "anteposed uterus in descensus" which presented the symptoms of a retroposition, it was possible, by properly placed tampons which forced the uterus as a whole well upward, relieving the drag on the cervical supports, to relieve the patient of all her symptoms. The placing of tampons being a temporary expedient, I determined to operate and suspend these uteri for permanent relief, although heretofore I had never opened the abdomen for the purpose of suspending an anteposed fundus. At the same time a further study of these cases was begun in the hope of finding other causes for the symptoms, and this study was carried out in the operating room after the abdomen was opened.

Opening the abdomen by a generous incision and widely retracting the wound, the pelvis is exposed by gently drawing back the intestines without disturbing the relations of the pelvic organs. On inspection, the following conditions are noted: In cases where the uterus as a whole is well held up in the pelvis by its cervical supports, *whether the fundus is in anteposition or retroposition*, there will be (1) no fullness, congestion or dilatation of the ovarian and anastomosing veins as they run through the infundibulo-pelvic and broad ligaments; (2) there will be present no drag on the parietal peritoneum covering the lateral walls of the pelvis, especially that part covering the infundibulo-pelvic ligament; (3) there is no tension on either the round or utero-sacral ligaments, which in turn are covered by parietal peritoneum; (4) there is no descent of the bladder nor engorgement of the vesicle veins.

Quite a different picture is presented in that group of cases in which the cervical supports have given away and the uterus as a whole has descended into the bottom of the pelvis, still without regard as to whether the fundus is antverted or retroverted. In this group of cases we see on inspection: (1) the ovarian and anastomosing veins full, congested and dilated, forming a so-called varicocele of greater or less intensity. This fullness and distention extends throughout the pelvic portion of these veins, but it will be noticed ends abruptly as the veins cross the posterior pelvic brim from which point upward they are normal in size. (2) The infundibulo-pelvic ligament and parietal peritoneum are put decidedly on the stretch, the chief drag coming from the posterior part of the pelvis at or near the attachments over the sacro-iliac joint. (3) The round and utero-sacral ligaments share in this drag. (4) The bladder has gone down with the descent of the cervix and the vesical veins have shared the general pelvic engorgement.

As striking as this picture is, still more striking is the picture presented by the following manipulations. Grasping the anteposed but descended uterus with forceps and bringing it up to the point where the suspension is to carry it, the following results are visible: (1) The ovarian veins and their anastomotic branches, being relieved of tension, immediately empty themselves and become normal. (2) The pull and drag on the sensitive parietal peritoneum is completely released. In a moment we can see exactly what our suspension is going to accomplish before we perform it. As like results are accomplished whether the fundus is forward or back, provided the uterus is in descensus, it follows that it is the descensus alone and not the version of the fundus which is the leading factor in the diagnosis of these conditions. The cervix remaining as a well suspended, fixed point, it matters not symptomatically whether the fundus is forward or back. But let the cervical supports give way and the uterus as a whole descends in the pelvis. This descent cannot take place except at the expense of pulling the parietal peritoneum and the blood vessels contained in it, and putting these structures on a stretch from the brim of the pelvis downward. The ovarian veins are the chief sufferers. They return most of the blood from the pelvic organs to the general circulation. They are long veins, they enter the vena cava and renal vein high in the abdomen and contain no valves. They have a great deal of work to do and are poorly equipped to do it. When the pelvic drag comes, stasis takes place below the point where the veins cross the pelvic brim and the blood is with difficulty returned, resulting in an engorgement of these vessels below this point. The parietal peritoneum is extremely sensitive to tension and in the cases we are discussing, this tension is greatest at the posterior pelvic brim. These two factors fully account for the symptoms produced by a uterus in descensus.

These facts have led me to suspend many anteposed uteri when symptoms have persisted which I have heretofore attributed only to retroposed uteri, but with very satisfactory results.

If, on examination before operation, the cervix is found low in the pelvis, the uterus as a whole low, whether the fundus is forward or not, and if the lower supports have given way, the pull must necessarily come, in some measure, on the parietal peritoneum which covers and forms a large part of the pelvic ligaments. Especially is this true with the infundibulo-pelvic ligament containing the ovarian vessels. Thus even an anteposed uterus, providing it is in descensus, may readily cause sacral backache and the bearing-down pains and feeling of fullness and weight due to partial occlusion and congestion of the ovarian veins. If one is in doubt as to whether an anteposed uterus is causing these symptoms or not, he has only to properly place a vaginal tampon which will force the cervix

up and hold it in position for forty-eight hours and note the result. If the symptoms of drag and backache are relieved by this procedure, then the surgeon is fully justified in suspending an anteposed uterus. It is the recognition of these symptoms *without* the presence of a retroposed fundus which is important. I have come to regard the position of the *fundus* as of little moment symptomatically, but I always determine the relative position of the *cervix* in the pelvis and base my judgment of whether a suspension is necessary or not upon the amount of descent of the cervical portion. I will cite only two cases:—

CASE 1. Mrs. B., 41 years old, 3 para. Chief complaint was sacral backache. She had not been able to sleep on her back for five years on account of this sacral backache which was just as bad when lying in that position as when on her feet. This is an important point and would be expected from the conditions above described, as there is no less drag when a patient is on her back than when she is on her feet. The night before operation she did not rest at all on account of this severe backache. Upon examination I found a relaxed perineum and lacerated cervix. The uterus was of normal size and anteposed, but the organ as a whole was in marked descensus in the pelvis. Again the term descensus must not be confused with the term prolapse. There is no prolapse in these cases and the cervix does not approach the introitus. By descent I mean a falling directly backward toward the hollow of the sacrum when the patient is in the dorsal position. I do not mean a rotation toward the outlet which is a much later stage, and an entirely different condition. The doctor who had referred the case did not believe a suspension should be done because the uterus was not retroverted. The patient had, however, every symptom of a retroversion, and believing that the repair of the lacerations alone does very little good in these cases, *i.e.* does not reach the cause of the trouble, the abdominal operation was urged and accepted. After repairing the cervix and perineum, the abdomen was opened and just the conditions above described were found. It was possible to demonstrate in a moment what the actual result of a suspension of even an anteposed uterus which is in descensus would bring about. The ovarian veins between the uterus and pelvic brim were engorged and dilated, while above the pelvic brim they were collapsed. The sensitive parietal peritoneum covering the infundibulo-pelvic ligament was tense and the pull came from a point just over the sacro-iliac joint. As the anteposed but descended uterus was raised, and the pressure at the pelvic brim relieved, the veins immediately emptied and the peritoneum relaxed.

From the moment the patient came out of ether she was relieved completely of her backache, which she had had for five years, and she has had no return. She had not the slightest backache even the first night after operation, nor during her entire convalescence.

The second case was that of a young married woman, 26 years old, who had never had children. The same condition was found, an anteposed uterus in descensus, the same drag and congestion of

ovarian veins demonstrated, and the same result after operation.

To offset these cases I will mention another, a woman, 38 years, two para., who also had sacral backache. The uterus was anteposed, and as her physician felt strongly that an abdominal operation was not necessary, I did only the plastics. She is at a loss to know why her backache is no better after the operation as she had been assured by her physician that it would disappear. This anteposed uterus should have been suspended.

The symptom of sacral backache is so common in women who have borne children and in women who have not, that it deserves close attention. Mistakes in diagnosis are made by us all. Many backs have been strapped, plaster jackets applied, belts worn, etc., by women with sacral backache in whom no retroverted uterus was found, but in whom descensus of an anteposed uterus was not recognized, and on the other hand many retroverted uteri, still well held up by the cervix, have been suspended when the patient should have had treatment by the orthopedic surgeon.

The observations made at the time of operation and the results that have been obtained by operation, have led to the conclusion that sacral pain and backache may be caused by a uterus in descensus regardless of the position of the fundus, provided that by this descent the pull is transmitted to the parietal peritoneum covering the ovarian vessels, forming the so-called infundibulo-pelvic ligament, and that *with* this pull there is present a stasis in the ovarian and anastomosing veins. This possibility should be borne in mind when examining a patient, whether the fundus is forward or not, and the amount of the descensus noted. A moment taken at the time of operation to inspect structures *in situ* is well spent and may lead to a more beneficial operative procedure than by following an accustomed routine. The effect of a suspension of the uterus should be noted as far as possible before the method of performing that suspension is determined upon.

It is far from my wish to leave the impression that every uterus, whether anteposed or retroposed, needs a suspension. As a matter of fact, the more clearly I differentiate my cases, the more conservative I become as to advising a suspension. Although the fundus may be retroposed, if the cervix is well held up, these cases seldom give symptoms and do not need any operative treatment. On the other hand, one should not hesitate to suspend a uterus already anteposed, provided the drop of the cervix with following descensus is present.

In summing up the situation it seems reasonable to conclude: (1) The position of the fundus is of little importance from a symptomatic standpoint. (2) Descent of the cervix, irrespective of the position of the fundus, causes drag on the parietal peritoneum of the pelvis with congestion of the ovarian veins. (3) We must

recognize this descent as a symptomatic factor and not hesitate to suspend an anteposed uterus when such descent is present. (4) In every case, before operating, we should prove by temporary means to the patient's and to our own satisfaction, that the malposition is the cause of the patient's symptoms. We will then suspend only those few selected cases where a suspension is necessary.

Medical Progress.

PROGRESS IN OPHTHALMOLOGY.

BY EDMUND W. CLAP, M.D., BOSTON.

RUPTURE OF THE GLOBE.

Fuchs calls attention to a class of ruptures of the eyeball often not recognized as such. Of course the ordinary ruptures from a heavy blow occur usually in the sclera concentric with the corneal margin and a little back from the limbus and are 10 to 12 mm. in length. They are most frequent above or above and nasal, rarely to the temporal side. The uniform location of these ruptures in spite of the variety of trauma which causes them is due to the weakness in the region of Schlemm's canal and the place where the anterior ciliary vessels penetrate the sclera. The internal break is there, while the external is further back, the tear is oblique. But there is another variety of rupture often overlooked. These are small, seldom greater than 2 to 4 mm., and while the internal break is at Schlemm's canal the external tear is at the limbus or even partially in the transparent cornea viz. perpendicular to the cornea or even obliquely towards the center of the cornea. These ruptures too, instead of being under the conjunctiva, invariably tear the conjunctiva. Almost constantly we find a small prolapse of iris. The internal injuries are less than in the case of typical rupture, hyphaema, small tears of iris or a partial iridodialysis and sometimes a rupture of the zonula of Zinn occur. Rupture of lens capsule is shown by a clouding of the lens coming on within a few weeks. This small rupture is more common in young people than in old. The prognosis is good, infection being rare. The prolapse should be excised and the iris replaced, which can be done unless a week has passed since the injury. Besides these, cases of incomplete rupture can occur in which a break happens at the canal of Schlemm and involves some inner layers of the sclera. The diagnosis is made certain later if a thin bluish line appears concentric with the limbus, which region may later become ectatic and the eye show increased tension. The pupil is often drawn up towards the rupture too.

BRAWNY SCLERITIS.

Stephenson reports a case and gives an excellent summary of what we know about a rare disease first fully described by Schlodtman from Fuchs' clinic as Brawny Infiltration of Conjunctiva and Sclera. I quote Stephenson's review as follows: Brawny scleritis has been called annular scleritis and gelatinous scleritis. It is a disease of middle life or old age and affects men more often than women. It runs a very chronic course with exacerbations of pain, lacrymation, photophobia and increased redness. At first a painless inflammation without known cause affects the anterior segment of the globe usually in both eyes though not perhaps beginning at the same time. The early stage may involve one portion of the circumference, though sooner or later there is a girdle about the cornea not extending beyond the curvilinear line which marks the attachment of the recti tendons. The infiltration is gelatinous and succulent, diffuse and has a reddish brown hue and is not usually nodulated unless the inflammation involves the insertion of the recti muscles. In the further course of the disease the infiltration spreads into the cornea, taking the form of a sclerosing keratitis. The anterior segment of the uveal tract becomes involved usually late in the disease as indicated clinically by keratitis punctata, posterior synechiae, occlusion of the pupil, vitreous opacities and lowered tension. Many of these eyes have come to pathological examination and in general dense infiltration of the sclera with mononuclear leucocytes and some polynuclear cells was found by all observers. Destruction of some lamellae of the sclera, giant cells and areas of fatty degeneration, peri and endarteritis have been present. Verhoeff pointed out that the findings in all reported cases are suggestive of syphilis. The appearance and course of the disease are fairly typical. Gumma of the sclera is an equally rare condition and would not be as diffuse nor would it last for years without breaking down. It would yield to proper treatment. Gunn described a monocular, probably gummatous infiltration of conjunctiva and episcleral tissue associated with secondary syphilis and promptly disappearing under anti-syphilitic treatment. This occurred in young people only and showed a zone of semi-translucent swollen conjunctiva of a pink or red color surrounding the cornea. Other writers have described a similar condition but it should not be confounded with brawny scleritis.

JUVENILE GLAUCOMA.

Löhlein has made a very extensive study of juvenile glaucoma and sums up as follows: Under juvenile glaucoma we include primary glaucoma of young people, sharply distinguished clinically from congenital hydro-phthalmus and perhaps more arbitrarily from glaucoma of

adults. We may draw the line at 35 years. Löhlein had ten cases of his own and collected 82 published cases. A few cases occur between the fifth and the tenth years, but a much greater number between 15 and 20, 40% of the cases occurred here, 10 myopic and 17 hypermetropic ones. Contrary to the incidence in adult glaucoma more males were affected than females and this is true also of buphthalmos. Sixty-two percent of all the cases were glaucoma simplex. Of all the cases 50% were myopic and a third of these had a myopia of more than six diopters while in glaucoma of adults myopia appears in not more than 15%. The statement that juvenile glaucoma is frequently monocular finds no support. It occurred in one eye only in 20%, which agrees with Wecker's statistics for adults. The resistance and power of adaptation of the tissues of youth accounts for a frequently very long prodromal stage. The passing of a regular astigmatism into one against the rule with the increasing tension would tend to contradict Schmidt-Rimpler's view that the astigmatism against the rule coming on in adults with glaucoma does not arise from the increased pressure but is merely a change of advancing age. Of course many cases of glaucoma in young people follow exactly the course of the disease in adults. One-fifth of the cases have the type with a deep anterior chamber and this variety may be a late modified buphthalmos. The frequency of myopia is explained by the increased tension causing an axial myopia in these young eyes from stretching.

Hereditry plays a great rôle in our cases for although not inquired into in all cases it is mentioned in 20%. The cause of most of the cases of juvenile glaucoma which are not simply adult glaucoma occurring in youth is to be found in some congenital defect or anomaly of development. In 50% we find defects such as persistent hyaloid artery, coloboma of iris, of lens, of nerve and lamellar cataract, all of which point to some fault of development which may also give rise to the glaucoma.

In the discussion of Löhlein's paper, Fuchs gave this classification of juvenile glaucoma: (1) True glaucoma with shallow anterior chamber in members of a family in which the disease is common and appears early. This type is identical with senile glaucoma. It is hereditary and familial; (2) Glaucoma caused by congenital malformations as buphthalmos; (3) Glaucoma with deep anterior chamber and myopia; (4) Glaucoma with deep anterior chamber and fine punctate keratitis, this is a secondary glaucoma but when the precipitates on Descemet's membrane are absent, it may be taken for a primary glaucoma.

RADIUM IN OCULAR THERAPEUTICS.

Koster has secured favorable results from treatment of various eye diseases with radium and mesothorium. He began in 1905. After

trying various methods he now uses a small glass tube containing five milligrams of radium bromide or four milligrams of mesothorium, though on the lids he sometimes uses a little ebonite box. The tubes are of thermometer glass with a little bulb blown on the end. Parenchymatous keratitis is treated from one-half to an hour, five to ten sittings with intervals of three, five, or seven days, according to the irritation. The cornea is not actually touched. The results were extremely favorable though other methods of treatment were used too. Leucomata of the cornea can be much thinned and if not too thick to begin with, the sight is much improved. Scleritis is favorably influenced in connection with other treatment. Not much result was obtained in retinitis pigmentosa or optic atrophy. When the sight is blurred by products of past inflammation the radium treatment of the back of the eye has a good effect. Vitreous opacities and hemorrhages clear up considerably. Cataract secondary to uveitis or choroiditis is favorably influenced but ordinary senile cataract is probably not changed by this treatment. Naevus pigmentosus and xanthelasma both disappear under treatment and epitheliomata were very successfully treated. All these diseases are either inflammations or hypertrophic growths, which accounts for the favorable action of radium in so many conditions.

Mattice reports the treatment of an epithelioma of the cornea with the barium carbonate salt of radium. A mica box container was applied to the tumor mass for six minutes and in a week a twelve minute application was made. Six weeks after the first treatment the tumor remains were given a fifteen minute exposure. The tumor which had covered the cornea and involved the conjunctiva had disappeared and the vision had improved from light perception to twenty-seventieths.

ETIOLOGY OF CHRONIC UVEITIS.

De Schweinitz at the seventeenth International Congress of Medicine discussed the pathogenesis of chronic uveitis excluding the syphilitic, tubercular and sympathetic varieties, deriving his material from an analysis of the literature for ten years past, an investigation of the views and experiences of American colleagues and a study of gastro-intestinal and auto-intoxication in relation to this affection. The frequency of primary uveitis varies from .9% to 2.4% and it seems more common in northern than in southern climates. As Stephenson said probably every case is of septic or of toxic origin. The infection may be exogenous or endogenous. After careful analysis of all described etiological factors he reaches the following general conclusions. Acute articular rheumatism is rarely if ever a cause of uveitis but various types of polyarthritides and myalgia may be associated with it, and be manifestations of

the same toxemia. We should not yet abandon the view that the same cause that produces gout may also produce a chemical inflammation of the uveal tract. It is possible that diabetes more rarely may do the same. There is bacteriologic and clinical evidence that the majority of cases of uveitis are caused by micro-organisms or their toxins. The gonococcus and the staphylococcus are the most important and the primary source of the latter is most frequently a chronic septic process in the mouth, tonsil, naso-pharynx, accessory nasal sinuses, in the uterine cavity or in the skin (boils, etc.) It is probable that in most instances living bacteria reach the uveal tract and they and their toxins cause the varieties of inflammation classified under the term uveitis. Indican in excessive amounts in the urine indicates intestinal putrefaction but other analyses must be made and if intestinal putrefaction dependent upon bacterial activity is present there is a source from which toxins may arise to cause uveitis. A thorough investigation of every patient's metabolism may lead to the finding of a group of diseases of the uveal tract caused by infections of bacterial origin arising in the intestinal tract.

DILATATION OF PUPIL FROM CORNEAL SCAR.

Zur Nedden has noticed that in superficial injuries leaving a large central scar of the cornea, the pupil of the injured eye often becomes larger than the pupil of the sound eye.

His cases occurred mostly after infected ulcers of the cornea which left a central dense scar covering the normal pupillary area. Of course anisocoria frequently occurs without any apparent cause or it may be due to diseases of the nervous system. But his cases had been under observation either before the injury or after the scar was freshly formed and no difference in the size of the pupils observed. The author carefully excluded any disease that could cause the anisocoria in his cases, or any weakening of the pupillary muscle from use of a mydriatic. In all of his cases the reactions of the pupil were prompt and normal in both eyes but the pupil of the affected eye was one and one-half to two millimeters larger in diameter and preserved this relative difference in shadow or in light or during convergence. This difference in size of the pupils came on only after a year or more; it was not seen three or four months after the injury. It was not observed in peripheral or eccentric scars, or in such large central ones that the eye was practically blind. The vision in these cases was decidedly improved by the larger pupil and this without any thinning of the scar. In two cases where the scar did get thinner the pupil remained larger. The author thinks it may be an attempt of nature to get better vision. At any event, it does not occur in every eye where it might be expected.

PROGRESSIVE FAMILIAL MACULAR DEGENERATION.

Darier has published the history of five cases of progressive familial macular degeneration and reviewed the literature. Stargardt in 1909 gave the history of two families, one of four persons all affected, and a second in which three out of five were affected. In these families there was no other familial ocular disease, the parents were well and not related. The trouble began with a central scotoma for red and green at 12 to 15 years without any fundus lesion, next came a relative scotoma and then an absolute one for white, and finally total loss of central vision. The periphery of the field remained normal for white and colors. The ophthalmoscopic signs began with an irregularity of pigmentation in the macula, of greyish yellow spots. Blotches and whitish streaks appeared and pigment spots like osteoblasts. The yellowish spots ended by fusing into a single horizontal oval spot varying in size from one-third the papilla to two or three times its size. This spot was outlined by pigment and attained its maximum about the twentieth year and then remained a long time stationary. Jennings in 1909 reported three cases in the same family, the parents being cousins. Batten had a similar affection in two brothers out of seven children. Lutz in 1911 reported a family of nine children, four of whom rapidly lost their vision about the twelfth year. Little yellow-gray spots mingled with pigment were seen in and about the macular region. Stirling in 1912 reported three cases in one family and Nettleship, 1909, and Doyne, 1899, have seen similar cases. Stargardt recently gave three new cases from one family. Now from 23 cases altogether, we may describe the course of this disease. The affection beginning about the twelfth year is insidious and progressive though rarely sudden in onset. In Darier's five cases it was slow in onset and has now been under observation 20 years. One may find no lesions of the fundus at first, or at times macular changes may occur before vision is affected. Central vision is always impaired, fine characters are lost first. The two eyes are attacked at the same time and the vision is nearly the same in each eye and fails equally. In some cases the loss of vision is rapid for a time and then remains at the same degree for a long period; in others, the failure is gradual for from 10 to 30 years. Lesions outside the macular region are exceptional. Stargardt thinks the process is one of degeneration resembling that in idiotic family amaurosis. Batten's two cases are of the maculo-cerebral type which begins early and goes into dementia. If the macular changes do not appear till 12 or 14, the brain is not affected. Syphilis may be safely excluded as a cause. This hereditary fault has not yet been found in several generations.

THE ELLIOT OPERATION.

The Elliot operation of trephining the sclero-corneal margin for glaucoma has received a great deal of attention this year and its limits are being defined. The papers on this subject are so numerous (over 200 this year alone) that only a few of the more important can be quoted. The more conservative authors would limit the operation to cases of chronic glaucoma which cannot be controlled by miotics, but the majority would advise trephining in all chronic glaucomas, and many favorable results have followed this operation in acute glaucoma, but iridectomy is preferred by the majority for acute cases. The dangers of the Elliot operation seem to be, injury to lens at time of operation, detachment of chorioid, so-called quiet iritis during the healing, and late infection via the conjunctiva over the trephine hole. Stephenson discusses some causes of failure after the operation; occlusion of the trephine opening by proliferation of tissue, or blocking by iris or ciliary body, lens, or vitreous; and intraocular hemorrhage which is rarer than after iridectomy. Detachment of the chorioid is usually temporary and of course occurs also after iridectomy, Lagrange operation or even after cataract extraction. Quiet iritis occurs, too, after ordinary iridectomy though often overlooked. Its evils may be avoided if atropine is used 24 hours after operation if the pupil is not well dilated or active. The accident of having the trephined disk drop into the anterior chamber has happened without evil results several times but Stephenson had a case which was followed by severe irido-cyclitis. As the operation is more used more reports of late infection are published.

Col. Elliot's latest article deals with some points of technic and with some objections to the operation. He believes that the vesicular type of filtration scar is to be avoided and when obtained is due to faulty methods of making the flap or splitting the cornea. The fluid escape should not be confined to a small area at and just about the corneal opening. The vesicular scar may be abraded during movements of the globe and it may give rise to infection from any organism that may be in the conjunctival sac. The flap should be as large as possible, beginning at the fornix above and the extremities kept well away from the limbus. Next only a small area of the flap must be actually dissected up, narrowing down at the limbus to just enough to give room to split the cornea and place the trephine. If the tissue at the sides is undamaged there will be normal subconjunctival tissue for extended filtration and the flap will be held in good position when released so as not to need a stitch. As we approach the limbus we should work a little deeper so as to make the base of the flap thick enough to avoid a vesicular scar, and so, too, the cornea should be split along the inter-lamellar spaces, not merely

cutting under the epithelium and Bowman's membrane. We cannot always avoid getting scars where the subsequent filtration is much more abundant in the region of the trephine hole, though this is not ideal, but we should not get a thin walled projecting vesicle whose cavity is in direct communication with the interior of the eye. Impaction of uveal tissue in the wound results from: (1) Undue traction during iridectomy, avoided by doing the iridectomy when the disc is cut, both disc and iris being seized together and cut off with the same snip of the scissors. (2) Sudden movement of the patient. (3) Forward movement of structures within, which mechanically push the iris into the trephine hole. (4) Iris being washed into the opening by the aqueous, this occurring after the patient has left the operating table. Col. Elliot thinks an iridectomy, a buttonhole opposite the trephine hole, should always be done. He thinks by using a 2 mm. trephine and not cutting the disc completely around we can regulate the size of the opening by completing the cut with the scissors, taking only part of the disc if we need only a moderate degree of filtration. The disc should be cut through completely at the corneal edge and hinged to the scleral side. Late infection has been reported in 14 cases so far and a great many trephinings have been done. Most of the cases are desperate and some risk is justifiable and the operation is not alone in having this danger.

THE EYE SYMPTOMS OF GENERAL PARALYSIS.

Uthoff from a large experience sums up the eye symptoms occurring in general paralysis as follows: Optic atrophy in 8%, optic neuritis in 2%, Argyll-Robertson pupil in 44%, unequal pupils in 22%, miosis in 25%, irregular pupils in 25%, ocular muscle paralysis in 10%. This incidence of optic atrophy is the same as in tabes. In all cases of progressive optic atrophy he has found in 95% signs of either tabes or of general paralysis and some of the excepted 5% had escaped from observation, which means that progressive optic atrophy is diagnostic of either tabes or general paralysis. Cases that remain confined to one eye are rare and probably not true progressive atrophy, but are secondary to syphilis of the brain. In both tabes and general paralysis the optic nerve changes are the same and are always associated with changes in the spinal cord. Hemianopsia is rare and suggests syphilis of the base. Optic neuritis and choked disc are not due to the general paralysis, but to basal syphilis and to hydrocephalus. Uthoff has not found characteristic macular changes. A unilateral Argyll-Robertson pupil has the same diagnostic importance as a bilateral. In recognizing anisocoria Uthoff did not take into account slight differences in size of the pupil, which are common in healthy individuals as well as are slight irregularities of the pupil.

PAROTID FISTULA FOLLOWING MASTOID OPERATION.

BY PHILIP HAMMOND, M.D., BOSTON.

ALTHOUGH it is well known that the mastoid operation is beset with difficulties, and that in performing it numerous structures may be injured, it would appear that the parotid gland is not subject to such injury. One does not think of it as lying in the course of the incision, and the writer has not been able to find any reference to it as one of the dangers to be avoided. While apparently unknown as a sequel to the mastoid operation, fistulae of the parotid gland are occasionally encountered by the general surgeon, and are considered to be extremely difficult to heal. The existence of such a fistula may be of exceeding annoyance to its possessor,¹ particularly in the case of a woman. The constant discharge of saliva renders one objectionable to his fellowmen, and the great increase during mastication necessitates satisfying hunger in solitude. The amount of fluid excreted may assume considerable proportions. Duphenix collected from a salivary fistula seventy grams of fluid in fifteen minutes, and a patient of Jobert's discharged several cupfuls in twenty-four hours. Attempts to close the fistula by cauterizing are recommended by some authorities before resorting to surgical intervention. The latter does not invariably cure, as it is extremely difficult to obtain a wound free from infection. Several successfully-operated cases are reported by Armstrong.²

The following case was brought to the attention of the writer at the Massachusetts Charitable Eye and Ear Infirmary, on July 7, 1913:

M. G., female, 9 years old. Five years before had had mastoid operation on right ear. Both ear and mastoid had healed in due course. The mother stated that during the past five years there had been a persistent discharge of watery fluid from the right cheek.

Examination revealed that the drum was healed. There was a depressed scar over the right mastoid extending nearly to the angle of the jaw. At the extreme lower end of this incision was a fistula so small as to be practically invisible. It was noticeable only as one saw fluid exude from it. The discharge was slight but constant, and was markedly increased while eating, or while chewing gum. The patient was kept under observation more than a week while exhaustive tests were made to establish beyond a doubt the fact that it was really a parotid fistula. On several occasions, potassium iodide ingested plain, and in capsule gave the starch reaction from the discharge within twenty minutes.

On July 22, 1913, under ether a piece of horse-hair was inserted into the fistula as far as it would go, about one-fourth of an inch. Using this as a guide, the tract was extirpated *en masse*, uncovering gland tissue. The incision was closed with three horse-hair sutures. The wound healed by primary union, and the sutures were removed on the fourth day.

The patient remained under observation until July 30, the eighth day following operation, when she was discharged from the hospital cured. I received a note from her parents on Nov. 24, 1914, in response to an inquiry, stating that she had remained well. This case is reported because of its exceeding rarity.

Book Reviews.

Essentials of Physiology. By F. A. BAINBRIDGE, M.A., M.D. (Cantab.), D.Sc. (Lond.), F.R.C.P., and J. ACWORTH MENZIES, M.D. (Edin.) With 134 illustrations. London: Longmans, Green and Company. 1914.

This excellent small text-book aims to compile in concise form the fundamental facts and principles of physiology for medical students. So far as possible, histologic details, descriptions of chemical and experimental methods, and matters of purely historic interest have been omitted. The Basle nomenclature is introduced throughout in brackets. Most text-books of physiology are so overburdened with details of the sort here omitted, as to be not only wearisome, but sometimes quite unreadable. The authors of this volume have shown their wisdom as well as their scientific knowledge and literary skill, by producing a convenient text-book in physiology which is actually attractive and interesting to read.

Cunningham's Manual of Practical Anatomy. Revised and edited by ARTHUR ROBINSON, Professor of Anatomy in the University of Edin-

burgh. Sixth edition. New York: William Wood and Company. 1914.

This sixth and latest edition of Cunningham's dissecting manual is welcome to students and teachers of anatomy. The text has been wholly revised, some of the figures altered, several new figures added, and a series of radiographs introduced. The chief alterations are in the section on the brain, which has been rearranged and largely rewritten. The first volume is illustrated with 249 figures in the text and 22 plates, 60 of which are in colors, and the second volume with 267 illustrations in the text and 11 plates. The Basle nomenclature is used throughout. The work thus adds to its former distinguished merits others which still further increase its already established standard of excellence and reliability.

Infant Feeding and Infant Metabolism. A Foundation for the Practitioner. By LEO LANGSTEIN and LUDWIG F. MEYER, Berlin. With 46 illustrations in the text. Second and third editions. Revised and enlarged. Wiesbaden: J. F. Bergmann. 1914.

This second and third edition of a standard German text-book on infant feeding has been delayed by the authors to enable the decision of various points in conflict and to permit the digestion and assimilation of the abundant additional material at their disposal. Fundamentally this work represents the pediatric principles upon which American methods of infant feeding are based, yet it is so cumbered with theoretic and laboratory details as hardly to be of available value to English-speaking practitioners.

Animal Experimentation and Medical Progress. By WILLIAM WILLIAMS KEEN, M.D., LL.D., Professor Emeritus of Surgery, Jefferson Medical College, Philadelphia. Boston and New York: Houghton Mifflin Company. 1914.

Mr. Stephen Paget's "For and Against Experiments on Animals" was reviewed in the issue of the JOURNAL for Nov. 14, 1912 (Vol. clxvii, p. 701). Dr. Keen's book is of much the same purpose and type. It consists of a series of fifteen essays, on topics connected with vivisection, which have previously appeared in various publications, one of them, on "The Influence of Antivivisection on Character," in the JOURNAL of May 2 and 9, 1912. There is a characteristic introduction by President Eliot. Like Mr. Paget's, this work "should prove a useful source of authoritative material for future defense of animal experimentation." Dr. Keen's facile literary style makes his book not only valuable but delightfully attractive.

THE BOSTON

Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JANUARY 7, 1915.

EDITORS.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

ANNOUNCEMENT.

THE announcement attached to the front cover-page of this issue calls attention to various changes in the administrative and editorial organization of the JOURNAL.

The appointment of a committee of consulting editors, it is believed, will result in an increased value of the editorial pages to the profession. From week to week members of this committee will contribute editorials commenting upon or interpreting important technical original articles appearing in the columns of the JOURNAL. They will also consult upon all matters of policy, so that the editorial conduct of the JOURNAL will represent, not the opinion of a few, but the collective judgment of a number of experts.

From its continuing affiliation with the Massachusetts Medical Society, the JOURNAL, as official organ of that association, will publish its proceedings, notices, news, and from time to time such editorial communications as the president or other officers of the society may wish to make to the profession.

An arrangement is also in process of development, whereby preliminary communications, and reports of clinical and laboratory research work done at the Harvard Medical School and allied hospitals will appear in these columns.

Editorially the JOURNAL will continue its policy of non-partisan comment on medical legislation and other current events of medical importance, seeking fairly to represent all sides of every question, avoiding personal controversy, aiming judiciously to reach wise decisions, to encourage tolerant discussion, and impartially to guide professional opinion. The new editor-in-chief assumes his duties with most grateful and appreciative respect to his predecessors in office; with reverence for the honorable traditions of the past, with consciousness of his responsibilities in the present, with hope that in future the JOURNAL, changing and adapting itself to the needs of new occasions, yet retaining its intrinsic and original character, may without interruption continue worthily to represent and serve the medical profession at home and abroad.

THE TESTS FOR MEMBERSHIP IN THE MASSACHUSETTS MEDICAL SOCIETY.

It is provided in the Acts of the Commonwealth that "no person shall become a member of the Massachusetts Medical Society except upon an examination by the censors of said society." It is further provided in the by-laws that the censors of each District Society shall meet at least twice a year for the examination of applicants, and that applicants shall not be considered as possessing the requisite qualifications for fellowship unless approved by at least three (of the five) censors. General uniformity of plan of examination in the several districts is secured by a Board of Supervising Censors, one being named by each district, who meet annually for the purpose of preparing the papers.

Most Fellows have joined the society shortly after completing their medical curriculum and at a time when they are probably best fitted to stand a written test in all of the ten or more subjects in which the censors usually examine. This examination is one of three, which for most men come in rather close succession, and which are all somewhat similar in scope,—the other two being the test set by the medical school for the degree, and that given by the State Board of Regis-

tration for the legal right to practise. The last of these three is the only one which is absolutely indispensable for medical practitioners in Massachusetts, where, unfortunately, by law the Board of Registration may not require the possession of a diploma as evidence that the candidate has received a proper medical or premedical education.

Membership in the State Society, however, carries with it so many advantages, educational, legal, ethical and social, that all qualified practitioners should seek it. What shall be done in the case of physicians who by reason of removal into the state after some years of practise elsewhere, or from neglect to make more timely application, find themselves in mid-life, while legally qualified practitioners, outside the pale of the society? Shall such persons necessarily be subjected to exactly the same kind of examination as the young men just out of the school? Fortunately these questions have been answered in the negative by many boards of censors in the past, thereby securing to the society many brilliant men, professors in our medical schools, public health officials and the like, who, after years spent in the pursuit of some branch of special medical study, would have forgotten so much of their unused mental equipment as to be unable to pass a written examination in all branches and who would frankly refuse to try to do so.

In the less conspicuous ranks of the profession there are a good many men who have been doing creditable, honest work in some branch of medicine, acceptable to their patients and approved by their professional neighbors. The censors have agreed that one-half the total value of the examination shall be given to written and one-half to oral tests. In the former category alternative questions might be proposed to these candidates. Every live doctor, after ten years of practice, may know less about some branches than he did on graduating, but should know much more about others. Give him a chance to select the subjects he will write about. And in the "oral" part of the test let the evidence both from himself and his medical neighbors count largely as to his fitness for membership. Men who have worked in the same town or on the same street with him should be able to give a pretty good idea of what manner of man he is. The Board of Censors is responsible eventually for his acceptance or rejection, but the collection of evidence about his work and character, while it may involve more labor than a formal written test, may yet be the most useful part of the

"examination." Moreover, while the law provides that the censors shall "examine," it leaves to their discretion what kind of examination in special cases is best adapted to learn the candidate's fitness.

It should be borne in mind that in many of the neighboring states the sole criteria for membership in the county and state societies are, (1) graduation from a good medical school, and (2) the passage of the state board examination, being two out of the three tests which, as above remarked, most of the qualified practitioners in Massachusetts must pass. Some of the censors are of the opinion that this would be an adequate requirement here. In that case the duty of the censors to "examine" would resolve itself into the verification of these two sorts of credentials and the investigation of the moral character of the candidate.

While the present system remains, however, it can be rendered more elastic, without any lowering of the intellectual or moral standard hitherto required, by simply recognizing in some cases the propriety of changing the methods of finding out the facts. The element of character should weigh heavily. In ten years of practise the character of a man has become pretty well fixed and can be generally better known than that of the neophyte who has been admitted to membership before he has had time to do much, good or bad. Only let us remember that if a person is to be admitted to the society in any degree upon his record, that record should be without a flaw. The advertiser, the fee-splitter, the abortionist, the pretender, should find the gate closed, the wall unscalable.

CHARLES F. WITHINGTON, M.D.,
President.

PTOSIS IN CHILDREN.

AN article on "Ptosis" by Dr. J. T. Williams, appearing in this issue of the JOURNAL, is a valuable review of the general subject and of methods of treatment.

It must be acknowledged that ingenious and skilful as have been the surgical attempts radically to correct the condition in adults, the results have not been as important or as uniform as could be desired. Other methods, medical, postural, mechanical, are purely palliative; and

if surgery fails we are forced to admit that well-marked cases will probably remain well-marked cases to the end of their days, to be relieved, perchance, of some of their discomforts, but not cured of the underlying condition. We speak now of the congenital visceral ptosis not of the acquired. The latter type while sometimes productive of quite as serious symptoms is more capable of cure.

Quite apart from the question as to whether congenital visceral ptosis is productive of symptoms in the child, its surprisingly common occurrence is a matter proved beyond cavil. It may be recognized not only by Roentgenological examination, but also by the general physical characteristics of the child. What shall we do about it? We may leave it alone and wait for growth and the upright position to increase the abnormality. On the other hand, after the child has assumed the upright position and an actual ptosis or a tendency to it is evident, we may strive by means of the development of muscles, by proper posture, and if necessary by means of mechanical supports to maintain a normal position of the viscera which growth will make permanent.

Though the symptom-complex of the condition frequently is associated with digestive upsets and malnutrition in children, it is in later life that we may expect fairly constant lack of physical endurance, the common "dyspepsias," and the occasional mental aberrations. We must admit the seriousness of the condition in the adult and the uncertainty of relief. If we can be persuaded of the possibility of cure in the child, surely this becomes a matter of preventive medicine whose importance can be measured only in terms of succeeding generations.

PROPOSED TRANSFER OF BOSTON QUARANTINE SERVICE.

IN last week's issue of the JOURNAL we commented editorially on the proposed transfer of the Boston Quarantine Service from municipal to federal control. This transfer was approved by the Boston Association for the Relief and Control of Tuberculosis. A special hearing on the subject was held on Friday, January 1, before the committee on ordinances of the Boston City Council. In a communication addressed

to this committee on December 28 the Boston Finance Commission makes the following statements and expresses the following opinion, which, as evidence of the expert judgment of this body, seems of value in determining the attitude of others on this question.

"On April 21, 1914, the Finance Commission recommended to the executive committee of the City Council that the quarantine service of the Port of Boston be transferred to the United States Government.

"The Commission said in that report, 'The service (quarantine) of Boston is almost, if not quite, as important to adjacent cities and towns, to the state and to adjoining states, if not to the entire country, as it is to the port of Boston. Recent acts of Congress have recognized the fact that quarantine service is a matter of national concern. The Act of Congress of Feb. 15, 1893, provides that "whenever the proper authorities of a state shall surrender to the United States the use of the buildings and disinfecting apparatus at a state quarantine station, the Secretary of the Treasury shall be authorized to receive them and to pay a reasonable compensation to the state for their use if, in his opinion, they are necessary to the United States."' Under this provision various cities and states have transferred their quarantine functions to the general government. The only cities of any importance which have not done so are New York, Boston and Baltimore.

"While Baltimore maintains its own quarantine service, the federal government also has a station, located at Cape Charles, and thus has direct control over all quarantine cases before the vessels reach Baltimore. The only cities, therefore, that have no federal supervision over quarantine cases are New York and Boston, and inasmuch as the commission understands that arrangements are about to be perfected for the transfer of the city of New York quarantine service to the Washington Government, Boston will be the only city in the country that is not under federal control.

"Under the federal statutes property belonging to the local service, when transferred to the United States, is paid for by the latter, and if a special appropriation of Congress is necessary before purchase a rental is paid until such appropriation is made. Under these provisions the quarantine station at Boston, including the boats and other property, may be sold to the United States, and the competent men now engaged in the local service may, under proper observance of civil service rules, be transferred to the public health and marine hospital service. The transfer would make for uniformity and efficiency in quarantine work; would free the commerce of Boston from the payment of quarantine charges, and would relieve the city of a large expense.

"It is the opinion of the best medical authorities that the war conditions existing in Europe will result in the spread of contagious diseases to the United States. Such a condition in the near future further emphasizes the recommendation made by the Finance Commission.

"The present quarantine service of Boston is inadequate to cope with the contagious diseases which will soon reach the port of Boston, and there must be a large and immediate expenditure of money to equip the present quarantine service to meet this emergency.

"The personnel of the staff is competent, but the service of the federal government would be better, because of the fact that the latter would be enabled to work in unity with the quarantine service of the whole country.

"The Finance Commission repeats its opinion as contained in its report of April 21, 1914, and recommends that both the present ordinance abolishing the quarantine service of the Board of Health, and the order providing for the transfer of the quarantine property to the United States Government, now pending before your honorable committee, be reported favorably."

The executive committees of the Norfolk and Suffolk Districts of the Massachusetts Medical Society, and of the Boston Homeopathic Medical Society, representing a membership of about 1400 physicians, have also unanimously endorsed the proposed quarantine transfer.

AMERICAN COLLEGE OF SURGEONS.

THE third convocation of the American College of Surgeons was held in Washington, D. C., on November 16, 1914, with the President, Dr. J. M. T. Finney in the chair. In his introductory remarks Dr. Finney stated that the subscriptions to the proposed endowment fund of \$1,000,000 already amount approximately to \$250,000. The Secretary, Dr. Franklin H. Martin, in presenting the roll of candidates, conveyed to the Fellows the greeting of Sir Rickman Godlee, president of the Royal College of Surgeons of England, with the gift from him of a gavel designed and used by Lord Lister. The list of new Fellows numbered 646. The honorary Fellows were Dr. Dudley P. Allen of Cleveland, Ohio; Dr. William C. Gorgas, U. S. A., of Washington, D. C.; Dr. Lewis S. Pileher of Brooklyn, N. Y.; Sir Thomas George Ruddick of Montreal; and Dr. J. William White of Philadelphia.

The fellowship address was delivered by Dr. Edward H. Bradford of Boston, Dean of the Harvard Medical School. Speaking on "The Higher

Education in Surgery" Dr. Bradford expressed the opinion that the American College of Surgeons should become an important agency in the advancement of American surgery through its influence on the better education and training of surgeons.

After concluding remarks by Dr. Finney, the meeting adjourned to an informal reception. At the first annual meeting of the college held on the afternoon of the same day, a number of committees were appointed and the report of the committee on examination for membership was received. This report is printed at length in another column of this issue of the JOURNAL. There were addresses by the secretary, by Dr. Finney, Dr. John B. Murphy of Chicago, Dr. F. D. Gray of Jersey City, N. J., Dr. John W. Long of Greensboro, N. C., and Dr. G. Sterling Ryerson of Toronto.

The following officers were elected for the ensuing year:

President—Dr. J. M. T. Finney.

First Vice-president—Dr. W. W. Chipman.

Second Vice-president—Dr. Rudolph Matas.

General Secretary—Dr. Franklin H. Martin.

Treasurer—Dr. A. J. Ochsner.

LEGISLATION ON CARE OF TUBERCULOSIS IN MAINE.

AT the opening of the Legislature of the state of Maine, on January 6, a bill was presented before that body providing for the establishment of a sanatorium for the treatment of persons infected with tuberculosis who are unable to pay for their care. There are already several state institutions for the tuberculous in Maine, but none where poor patients can go without charge.

In their estimates for the years 1915 and 1916, which were filed at the office of the state auditor in Augusta, Me., on December 26, the directors of the Maine Association for the Relief and Control of Tuberculosis advocated the establishment of an institution for advanced cases and also of a commission to study and direct the work of tuberculosis prevention.

The proposed act referred to above, aims to carry out these recommendations. It provides for an institution to be known as the Maine State Sanatorium for Tuberculous Patients and to have a government vested in a board of hospital trustees.

"The proposed act also provides that all persons who are proper subjects for this sanatorium, who are unable to pay the fixed charges of the institution, upon recommendation of the municipal officers of the city or town of which the patient is a resident, may be admitted free of charge. All other persons who are proper subjects shall pay \$4.50 per week.

"Under the bill, the board of hospital trustees shall select and purchase a suitable site for the sanatorium and shall proceed as soon as practicable to erect and furnish and equip suitable buildings. The bill carries \$100,000 to be used within the next two years.

"As an alternative for the state to appropriate \$35,000 for the year 1915 and \$55,000 for the year 1916 for the sanatorium at Fairfield, the directors suggest that the state take over this institution, which has cost the Association about \$25,000, the state to pay approximately \$15,000 or a sum equal to the estimated indebtedness at the beginning of the year 1915 and that the institution at Fairfield be one of several of the kind which should be supported and managed by the state."

In the conclusion of their report the directors of the Maine Association for the Relief and Control of Tuberculosis speak as follows of the tuberculosis situation in that state:

"The fact that approximately 10 per cent. of the deaths in the state are from tuberculosis entitles this work and the suppression of this plague to an immediate and earnest consideration.

"The five years' experience of the members of this association has convinced us that the needs of the state in handling the tuberculosis situation are infinitely beyond the ability of private institutions or individuals to handle.

"The number of patients at the Fairfield Sanatorium is thirty. The present average cost of a patient is about \$15 per week. With added equipment to care for sixty patients, and funds with which to take advantage of cash discounts and other economies, the cost could probably be reduced to \$10 or \$12 per week, which is the average cost in some of the large institutions in Massachusetts.

"Many applications have to be refused because patients pay but \$2 or \$3 per week, and a large number are refused because they can pay nothing. Many other applicants are refused because they are in an advanced stage of the disease and cannot be well treated in the same building with early cases."

MEDICAL NOTES.

LONDON DEATH-RATES IN NOVEMBER, 1914.—Statistics recently published show that the total

death-rate of London in November, 1914, was only 14.6 per 1000 inhabitants living. Among the several districts and boroughs the highest rate was 20 in Finsbury, a populous central slum, and the lowest was 10.4 in Lewisham, an open southern section of the city.

APPOINTMENT OF DR. MOYNIHAN.—It is announced that Dr. Sir Berkeley Moynihan, of Leeds, England, has been appointed consulting surgeon with the British forces overseas, and left London for France on Dec. 4, to assume his duties.

AMERICAN UNIVERSITY REGISTRATION STATISTICS.—The registration statistics of thirty American universities for 1914, published in the issue of *Science* for Dec. 25, show that, including summer-session enrolment, the first eight are Columbia, California, Chicago, Wisconsin, Pennsylvania, Harvard, Michigan, and New York. Exclusive of summer students, the order is Columbia, Pennsylvania, California, Michigan, New York and Harvard. The largest medical school is that of New York, with 439 students. The Michigan medical school has 378, Johns Hopkins 374, Columbia 378, Tulane 343, Harvard 321, Pennsylvania 290, Illinois 287, and Ohio 281.

SANITARY PROGRESS IN NEW YORK.—Report from Albany, N. Y., states that on Dec. 25 the governing board of the state board of health issued an order forbidding the use of common drinking-cups and roller-towels in public places, and fixing sanitary rules to govern barber shops, manicure parlors, and chiropodist offices. This order is essentially the same as those already adopted in several other states and enforced on interstate railroad trains.

MEDICAL STUDENTS IN SWITZERLAND.—In the summer of 1914 the total number of medical students in the Swiss universities was 2205, of whom 327 were at Bâle, 117 at Berne, 879 at Geneva, 316 at Lausanne, and 566 at Zürich.

OREGON EUGENIC MARRIAGE LAW.—An item in the Philadelphia *Bulletin* notes that a recent convention of county officials in Oregon voted its unanimous disapproval of the present so-called eugenic marriage law in that state, requiring a physical examination of all male applicants for matrimonial licenses. Its repeal is advocated on the ground that it has proved ineffective and even harmful.

THE EPIZOOTIC OF FOOT AND MOUTH DISEASE.—On Dec. 23 the federal quarantine for foot and mouth disease among cattle was raised from the following counties of Illinois: Alexander, Bond, Calhoun, Crawford, Clay, Clinton, Edwards, Effingham, Fayette, Franklin, Gallatin, Hamilton, Hardin, Jackson, Jasper, Jefferson, Jersey,

Johnson, Lawrence, Macoupin, Madison, Marion, Massac, Montgomery, Monroe, Perry, Pope, Pulaski, Randolph, Richland, St. Clair, Saline, Union, Wabash, Washington, Wayne, White and Williamson.

In the following counties, upon which the quarantine is modified, cattle may be received and shipped for immediate slaughter: Brown, Clarke, Christian, Cumberland, Greene, Pike, Shelby and Scott.

An absolute quarantine was ordered against Tuscola county, Mich., and Tioga county, N. Y.

In Connecticut the quarantine has been modified over all the state, except the counties of New Haven and Hartford, to permit the cattle to enter for any purpose and to be shipped out for immediate slaughter.

POLIOMYELITIS IN VERMONT.—The weekly report of the United States Public Health Service for Dec. 18 states that during October, 1914, there were 55 cases, and during November, 9 cases of poliomyelitis in Vermont.

CHOLERA IN SILESIA.—During the fortnight from Nov. 15 to 28 inclusive, 1914, 33 cases and 9 deaths of Asiatic cholera were reported among troops of the Austrian army in Silesia, Germany.

TUBERCULOSIS CAMPAIGN COSTS TWENTY MILLIONS.—The annual statistical statement of the National Association for the Study and Prevention of Tuberculosis, issued on Jan. 2, shows that over \$20,500,000 were spent last year in the campaign against tuberculosis in the United States. Of this sum, 66.8 per cent. was derived from public funds, either federal, state, county or municipal, and the remainder was contributed by private philanthropy.

Institutional care and treatment of consumptives in hospitals and sanatoria makes up the largest share of the total expenditures. More than \$17,300,000 were spent for this purpose, with an additional \$925,000 for special treatment of tuberculous insane and prisoners. These figures include not only the cost of maintenance, but in some instances the cost of construction of institutions. Anti-tuberculosis associations spent the next largest sum, amounting to a little over \$900,000. Care of patients in dispensaries and by visiting nurses cost almost as much, approximately \$860,000. The growth of the open air school movement is shown in the fact that last year more than \$300,000 were spent for this purpose, as against \$10,000 expended five years ago. State and city boards of health spent \$200,000 directly on tuberculosis work.

In the last five years, the percentage of money spent from public funds has steadily increased from 53 per cent. in 1909 to 69.3 per cent. in 1913, and 66.8 per cent. last year. The National Association considers this increase significant, since it indicates a shifting of the burden of in-

stitutional care of the consumptive from the private purse to the general public purse where it rightly belongs.

New York spent more money last year in the tuberculosis campaign than any other two states in the Union, due largely to the increased and rapidly-developing movement for city and county care of the tuberculous. Pennsylvania, which has occupied second place for the past four years, was superseded last year by Illinois, with Massachusetts in fourth place and Colorado in fifth place.

EUROPEAN WAR NOTES.—In a recent letter to the public daily press, Mr. Robert Bacon has called renewed attention to the needs of the American Ambulance Hospital at Paris:

"The American Ambulance Hospital in Paris has cabled an urgent appeal for more volunteers to drive motor ambulances in France; 180 men and 100 ambulances are wanted as soon as possible.

"A word of explanation of what the American hospital is: Its present organization consists of the main hospital at Neuilly, on the outskirts of Paris, located in the Lycée Pasteur building, which had just been completed at the outbreak of the war. It is at present equipped with about 450 beds. A second hospital unit has also been established at a point nearer the firing line, about 20 miles from Paris. This contains about 200 beds.

"In addition there is a flying ambulance corps, consisting of about 60 motor ambulances.

"To enlarge this work and increase its effectiveness a call for volunteers is now made. The reports from the surgeons working in the hospital show that the majority of the cases brought to them have been so delayed in reaching medical assistance that gangrene and blood poisoning have frequently unnecessarily set in, and that some of those only slightly wounded have succumbed because of inattention before reaching the hospital.

"To date each ambulance has averaged the transportation of over 50 wounded a day, and there are many emergency calls when they are pushed to the fullest extent of their endurance. It is not especially easy work, and every volunteer is subject to the military discipline of the organization."

Report from Philadelphia on Dec. 28 states that Dr. J. William White, a trustee of the University of Pennsylvania, has announced that the university is preparing to send to Paris eight or ten surgeons to take charge of a ward of the American Ambulance Hospital, endowed by Philadelphia citizens.

Report from Cleveland, Ohio, on Dec. 28 announced plans for an expedition to be sent to the American Ambulance Hospital, Paris, by the Western Reserve Medical School and Lakeside Hospital, and on Dec. 30 this expedition sailed for Europe. The expedition is to be

financed by trustees and other friends of the two institutions. Its personnel will consist of Dr. George W. Crile, professor of surgery, Western Reserve University, and visiting surgeon of Lakeside Hospital; Dr. Samuel L. Ledbetter, Dr. Edward F. Kieger and Dr. Le Roy B. Sherry, now of the resident staff of Lakeside Hospital, who will act as assistant surgeons and clinical assistants; Dr. Lyman F. Huffman of the resident staff of Lakeside Hospital, who will act as clinical pathologist; Dr. Charles W. Stone, assistant professor of nervous diseases in Western Reserve University, and visiting neurologist of Lakeside Hospital; Miss Agatha Hodgins and Miss Mabel L. Littleton, anesthesiologists; Miss Iva B. Davidson and Miss Ruth J. Roberts, from the operating-room staff of Lakeside Hospital.

Dr. Crile takes with him also, to assist in a special research, Miss Amy F. Rowland, B.S., Mt. Holyoke College, and William J. Crozier, Ph.D., Edward Austin Fellow of the department of zoölogy of Harvard University.

On Jan. 1 the total of the New York Belgian relief fund amounted to \$697,416.17; the New York Red Cross fund to \$415,019.83; the German relief fund to \$323,050.00; and the American Jewish relief fund to \$237,881.93.

The New England Belgian relief fund amounted to \$164,086.89; the Massachusetts Red Cross fund to \$94,416.22; the Boston branch of the American Ambulance Hospital fund to \$48,793.95; the Boston Jewish relief fund to \$23,647.85; the Russian relief fund to \$9570.00; and the Polish relief fund to \$9052.91.

BOSTON AND NEW ENGLAND.

SMALLPOX IN EVERETT.—Report from Everett, Mass., states that two cases of smallpox were discovered in that town on Dec. 27. The couple have been isolated in their home, and about 350 contacts were vaccinated.

FIRE IN NEW HAVEN HOSPITAL.—Report from New Haven, Conn., states that on Dec. 27 a fire broke out in the Grace Hospital of that city. The seven patients in the portion of the building involved were rescued by nurses. The damage is estimated at \$10,000.

NEW ENGLAND BAPTIST HOSPITAL TRAINING SCHOOL.—The trustees of the New England Baptist Hospital have issued invitations to the graduation exercises of their training school for nurses to be held on Thursday evening, Jan. 7, 1915, at 8 o'clock, in Kingsley Hall, Ford Building, corner of Bowdoin Street and Ashburton Place, Boston. The principal address will be made by Dr. Joel E. Goldthwait, of Boston, and diplomas will be presented to a class of nine nurses by Colonel Edward H. Haskell, president of the board of trustees. Dr. George S. C. Badger, chairman of the training school committee, will preside.

HOSPITAL BEQUESTS.—At the recent 35th annual meeting of the Lynn (Mass.) Hospital, announcement was made of a gift of \$100,000 for a nurses' home from Mrs. Luther S. Johnson, of that city.

The will of the late Sara E. Woodworth, of Boston, filed in the Suffolk probate court on Dec. 26, contains a bequest of \$6000 to the Free Hospital for Women, Brookline, Mass.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Dec. 29, 1914: Diphtheria 66, of which 1 was non-resident; scarlatina 40, of which 6 were non-resident; typhoid fever 4; measles 50; tuberculosis 43, of which 4 were non-resident. The death-rate of the reported deaths for the week was 16.95.

6. Lumbard holds that the chief factor in the causation of nausea and vomiting after ether or other anesthetics is the smell of the anesthetic. He has devised a cigarette-shaped piece of gauze which can be fastened to the face by adhesive plaster in such a way that it just projects beyond the tip of the nose. By keeping this gauze saturated during an operation with some pleasant perfume, e.g. oil of bitter orange peel, he has been uniformly successful in preventing post-anesthetic nausea. [L. D. C.]

12. BRIGGS, LER. H. *The Neutrophilic Blood Picture in Pernicious Anemia: A Preliminary Report.*

1. Schmidt contributes a careful discussion of the evidence as to the etiology of pernicious anemia, with special reference to that suggesting that a hemolytic agent derived from the gastro-intestinal tract is responsible, at least in some of the cases. It is shown that the gastric achylia in certain instances has been proved to exist before the appearance of the anemia, and that the diarrhea present in a third of a series of cases preceded the development of the anemia by many years. While no constant anatomical changes are demonstrated, the author supports the view that degenerative changes in the mucous membrane of the small intestine produce hemolytic lipoids, which have been extracted by Berger and Tsuchiya in his laboratory. In treatment he advises a diet avoiding irritants, finely divided and easily assimilable, limiting carbohydrates or proteins according as the stools are acid and fermenting or alkaline and putrefactive. Stress is laid upon the regular use of hydrochloric acid with meals and upon gastric and duodenal lavage.

3. Fitz's paper deals first with Schlayer's tests of renal function, by which, as in illustrative cases, it is shown that delayed excretion of lactose, injected intravenously or intramuscularly, is indicative of vascular nephritis, whereas delayed outputs of sodium chloride and of potassium iodide point to tubular nephritis. These tests have been shown to reveal abnormal conditions in advance of clinical symptoms which have later developed. Of wider application in determining the severity of the disorder in cases with symptoms, however, is the phenolsulphonethalein test, by means of which with few exceptions information may be obtained as to the total renal function. To minimize the occurrence of error in these exceptions more than one test must be used. The determination of the incoagulable nitrogen and urea in the blood is of importance. Determinations of signs of acidosis in blood, urine and expired air may prove of significance. By the results of these tests the dietetic treatment may be made more rational, giving a salt-poor diet in cases with poor chloride elimination, limiting protein in cases unable to excrete nitrogen, and giving alkalis in cases with acidosis.

4. Schleiter reports upon a series of cases given intravenous doses of strophanthin, some being cases with regular hearts, while others were cases of auricular fibrillation or other irregularities. While the tracings given are not all conclusive of the diag-

noses, and little attention was paid to the effect on blood-pressure, the observations are of distinct interest. It is concluded that the action of strophanthin administered intravenously is similar to that of other members of the digitalis group administered orally, but more rapid. It showed a decisive effect in all cases of auricular fibrillation, and is recommended in severe cases of this condition to tide the patient over until digitalis by mouth takes effect. In the series with regular hearts its action was not striking. The maximum dose is 1 mgm. In two cases of paroxysmal tachycardia its use was followed by cessation of the attack.

5. Goodman and Lüders have applied Bastedo's test of colonic inflation to induce tenderness at McBurney's point, proposed as a sign of chronic appendicitis. While they failed to obtain a positive test in any of 75 control cases, in three with abdominal symptoms who reacted positively, no appendicular lesion was found. Twelve of the negative cases had diseased appendices, five having acute appendicitis. They conclude that the test is not without value, but that it should be regarded as merely an aid to diagnosis to be given only minor consideration.

7. Stoll and Heublein discuss the occurrence and diagnosis of tuberculous bronchial glands, particularly in children. They conclude that up to the fifteenth year this is the commonest form of tuberculosis. The early symptoms are chiefly toxic, although cough is generally present. Signs of apical disease are not to be expected. The most significant sign in their opinion is whispered bronchophony over thoracic vertebrae as described by d'Espine.

9. Hopkins and Zimmermann have done a large number of Wassermann reactions comparing the lipid and the cholesterin antigens. The results seem to show that the cholesterin antigens, while increasing the sensitiveness of the test, involve a risk of error which should not allow them to be used to the exclusion of the less sensitive extracts of the original test.

13. WOHL, M. G. *Granuloma Fungoides.*

1. Miller has conducted experiments with the object of testing the influence of expectorant drugs upon the bronchial secretion in dogs. While his results are not convincing as to the action of the drugs in man, he concludes that ammonium carbonate, ammonium chloride, apomorphine and ipecac when given in sufficiently large doses to animals increase bronchial se-

cretion, but that in doses equivalent to ordinary human therapeutic doses no increase occurred.

2. Hall calls attention to the occurrence of relative pulmonic insufficiency, especially in advanced cases of mitral stenosis, a condition which has been seldom mentioned in the literature. He believes it to be found in perhaps 3 to 5% of the cases of mitral stenosis. It is to be detected by the presence of a soft diastolic murmur in the pulmonic area, disappearing as compensation is regained but reappearing as decompensation reappears; with exertion or with expiration, particularly with the glottis closed, it is intensified. The pulmonic second sound is commonly enfeebled.

3. Taussig has investigated 66 cases of vulvovaginitis in children. In the etiology he finds reason to suspect that infection from the lavatory seat is an important factor. In treatment he had the best success with, in acute cases, rest in bed for two weeks with injections of 25% argyrol twice a day; in the second and third weeks the argyrol was replaced by 1% silver nitrate, later changed to 2%, or even 4%, at increasing intervals, until there is no discharge for a month. He urges the adoption of public health measures to diminish the spread of the disease from one child to others.

4. Einhorn reports deductions from his experience with duodenal contents withdrawn by tube for examination. The macroscopic appearance of bile is of significance, golden yellow clear bile usually indicating a normal gall-bladder, whereas fresh bile that is greenish yellow and somewhat turbid suggests disease of the gall-bladder and gall-stones. Study of ferments permits gauging pancreatic function. Constant absence of one ferment usually indicates chronic pancreatitis. Absence both of bile and of pancreatic juice suggests obstruction at the papilla, whereas absence of bile only shows a higher obstruction.

9. Friedman attempts to show differences of diagnostic value in the blood pictures of gastric ulcer, duodenal ulcer and appendicitis. His results, however, are not sufficiently constant to deserve more than partial reliance in clinical diagnoses.

11. Howell advocates the use of pituitary extract in pneumonia, not only for its direct effect in raising and supporting blood pressure, but also on account of its action in combating tympanites. He feels that the existence of diarrhea should not be taken as a contraindication. [F. W. P.]

1. Clark's article is in the main a protest against the older teaching that in a large proportion of cases gall-stones cause no symptoms. He urges their removal whenever their presence is known.

3. Lichty calls attention to the occurrence of severe hemorrhages in gastric and duodenal ulcer when food by mouth has been withheld. He concludes that in acute ulcer or in acute exacerbations of chronic ulcer, feeding by mouth should not be suddenly discontinued.

5. Sachs, Strauss and Kaliski report upon 120 cases of syphilis of the nervous system treated by them, in part by salvarsan intravenously supplemented by mercury, and in part by intraspinal use of salvarsanized serum. The latter treatment, however, does not seem to them to possess advantages over the intravenous method. With regard to results the authors feel that in tabes dorsalis in most cases the subjective condition of the patient can be greatly improved and the progress of the disease checked. In cerebral and cerebrospinal lues the results of salvarsan treatment combined with mercury were better than were secured by any previous methods. The results in general paresis were less satisfactory.

7. Veeder reports five cases of duodenal ulcer in infants, four with autopsy, and summarizes the literature.

9. Churchman reports two observations of interest: the finding of tubercle bacilli by examination of washings of the bladder in a case of tuberculous ulcer, and the finding of tubercle bacilli in the urine of a case proved by autopsy to be general miliary tuberculosis.

10. Clark, from a small series of cases and from the literature, concludes that the test for albumin in the sputum in tuberculosis deserves a wider application, with reference both to diagnosis and to prognosis. In diagnosis its worth is still unproved and its presence may be misleading; it seems, however, to be positive in all cases of tuberculosis where the sputum is positive, and in general to vary in amount of albumin, according to the degree of the exudative or destructive process. 1. Thayer and Snowden report a study of 54 cases in which the phenolsulphonphthalein test of renal function performed a variable period before death has been compared with the condition of the kidneys at autopsy. In cases of severe chronic nephritis a low phthalein output was found in all. In cases of chronic passive congestion from heart disease the phthalein elimination was often considerably reduced, but as a rule rose with the establishment of circulatory compensation. In the few instances of chronic nephritis

of moderate extent the phthalein excretion was considerably reduced. In one case of acute nephritis and in one case of amyloid disease the excretion was greatly reduced, and in some instances of cloudy swelling in acute infections considerable reductions were observed. The article lends strong confirmation to the value, both diagnostic and prognostic, of the test.

2. Wilson and McDowell report that of 399 cases of gastric cancer in which resections were performed, 52% showed definite evidence of association with ulcer; while in the remainder the evidence of association with ulcer was not conclusive, from a study of clinical histories combined with examination of surgical and autopsy specimens, it is concluded that gastric cancer rarely develops except at the site of a previous ulcerative lesion.

3. Moffitt reviews the literature of splenectomy in pernicious anemia, collecting 31 reported cases, to which he adds two original ones. While he agrees with Klempirer and von Decaslello that we have in the operation a means of bringing about a remission of the disease fairly certain when other means have failed, the facts that 8 of the 33 cases died immediately or soon after this operation and that certain cases have not been benefited, together with the fact that improvement may occur without treatment, even in the worst cases of pernicious anemia, are to be considered before splenectomy is advised.

4. Lynch and Draper discuss the subject of surgical alterations of the course and function of the colon, and describe operations which they propose to avoid the harmful effects of ileosigmoidostomy and other similar procedures as they have hitherto been performed.

5. McCrae reports his experience with the subcutaneous injection of oxygen. While the results in eleven cases of pneumonia were disappointing, in cardiac and renal dyspnea notable relief was usually obtained. It seemed of benefit also in accidents of anesthesia, edema of the lungs and glottis, obstruction of the upper respiratory tract, asphyxia at birth, syncope and electrocution.

7. Palmer from study of a case of extensive resection of the small intestine records the following observations: The loss of nitrogen in the stools was four and five times the normal, and the loss of fat five to six times the normal. There was a high urinary indican. Ammonia formed a much larger part of the urinary nitrogen than normal. [F. W. P.]

in South Carolina. They found that the disease spread from a pre-existing case as a center in these six villages. It was transmitted to new victims only through very short distances and chiefly to those immediately associated in the home with a pre-existing case. Frequent use of corn-meal as an article of diet was found not to be an etiological factor in these cases. No evidence was discovered that canned goods have anything to do with the causation of pellagra. Frequent, even daily, use of fresh meat and of eggs afforded no relative protection from the disease. The daily use of milk seemed to diminish somewhat the danger of contracting pellagra.

4. Staines, James and Rosenberg studied the effect of changes in altitude on the lymphocytes of the blood in students and monkeys. They find that at an elevation of 6000 feet the larger lymphocytes are absolutely increased by at least 20%. The basophilic mononuclear elements in the blood at sea-level are about 34%, and at 6000 feet about 42%. The total leucocyte count is approximately the same at both levels. The total polymorphonuclear cells diminish in number in exact proportion to the increase in the number of mononuclears. There is an increase of 22% in the number of erythrocytes at an altitude of 6000 feet.

8. Batherwick reports on an elaborate study of the influence of foods on the composition of the urine. The true acidity of the urine is due to an excess of H+ ions in the excretion. A surplus of OH ions produces alkalinity, and when there is an equal number of H+ and OH ions present the solution becomes neutral. An increase in H+ is accompanied by a significant increase in the ammonia excretion. The solubility of uric acid in urine is closely dependent on the H+. All urines with an acid reaction are supersaturated with uric acid, while alkaline urines are capable of dissolving added uric acid. Foods with a predominance of acid-forming elements increase the urinary acidity. Rice and whole-wheat bread increase urinary acidity. Plums, prunes and cranberries, although yielding a basic ash, nevertheless increase the acid formation because of their benzoic acid content, hippuric acid being formed. Foods which have a preponderance of basic elements lead to the formation of a less acid urine. Potatoes, oranges, raisins, apples, bananas and cantaloups are very efficient in reducing the acid output. Tomatoes are of less value in this respect. [L. D. C.]

1. Siler, Garrison and MacNeal studied the relation of methods of disposal of sewage to the spread of pellagra in South Carolina. They found that pellagra morbidity was higher in congested communities using surface privies than in more sparsely settled districts in which similar methods for the disposal of excreta were employed. In the city of Spartanburg the endemic foci of pellagra were located in the districts in which surface privies were in use. In cotton-mill villages equipped with surface privies pellagra was found to be endemic and new cases arose there year after year. In two villages completely equipped with water-carriage systems of sewage disposal it was impossible to find cases which had certainly originated there. Some evidence was found that pellagra spreads in hospitals for the insane more readily in the wards housing untidy patients. The writers conclude that methods of disposal of human wastes may be a determining factor in the spread of pellagra and such means of prophylaxis against this disease should be thoroughly tested.

5. Friedman and Strouse made a clinical study of carbohydrate tolerance tests in a large number of cases in which a functional disturbance of any of the ductless glands was thought to exist. They conclude that while these tests may indicate in a general way functional disability of an organ under suspicion, they can never be interpreted in an absolutely specific manner, for other organs may be involved. Functional inefficiency of one gland sufficient to lower the threshold of carbohydrate metabolism may be entirely compensated for by functional hyperactivity of a correlated gland.

6. Rosenbloom and Andrews estimated the potassium content of the cerebrospinal fluid in normal persons and in cases of paresis, cerebrospinal syphilis, dementia precox, alcoholism, meningitis, encephalitis, typhoid fever and neurasthenia. They find that the potassium content is not increased in degenerative diseases of the cerebrospinal system but is high in the acute cases. The test, however, is of no material value in diagnosis. According to the writers' observations, the potassium content of uncentrifuged cerebrospinal fluid was higher than that of centrifuged fluid. No relation was found, however, between the number of cells in the fluid and its potassium content, or between the potassium content and the globulin reaction.

9. Walker presents clinical evidence to show that cholesterolized alcoholic extracts of human heart have a specific fixation property with syphilitic sera and that they do not give non-specific fixation with non-syphilitic sera, provided the re-agents are accurately titrated. The serum of a syphilitic patient contains something for which cholesterol has a definite fixation power in the presence of complement.

10. Wilbur and Ophüls report twelve cases of botulism, one fatal, due to the eating of domestically prepared canned string beans served without preliminary heating. The methods of sterilization under pressure in use by canning factories seem to prevent the growth of *B. botulinus* in their pack. In the fatal case reported the gross autopsy findings were negative except for moderate hyperemia of the cerebral vessels, especially at the base of the brain and in the region of the fourth ventricle. There was marked hyperemia of the viscera, especially the liver, kidneys and intestines, and bronchopneumonic lesions of the lungs. Microscopic examination of the brain showed many vascular thromboses, especially about the brain stem and involving the nuclei of most of the cranial nerves. Such lesions explain the clinical phenomena better than the hypothesis of a specific action of botulin on certain ganglion cells. [L. D. C.]

3. *TSCHERTKOFF, J. *Indicanemia and Uremia.*
4. *HAFEMANN, G. *The Albumin Content of Tuberculous Sputum.*
5. RAUDNITZ. *A Substitute for Milk of Almonds.*

3. Tschertkoff has tested the blood serum for the presence of indican as a sign of impending uremia. The method used consisted in precipitating the albumin with trichloroacetic acid, filtering, and testing the filtrate for indican by Obermayer's re-agent. At the same time the blood urea was estimated. Tschertkoff finds that in nephritis without renal insufficiency there is never a significant urea retention nor is indican present in the serum. When, however, the blood urea reaches a certain concentration, indicanemia is found. Thus indican in blood serum affords the same unfavorable prognostic information as increased blood urea.

4. Hafemann has analyzed the albumin content of 171 sputa, and has compared these findings with sputum examination for tubercle bacilli. From his results, he concludes that more than one albumin test must be made to allow for any deductions, and that if bacilli are found, albumin is always present. He feels that the most probable reason for this is that the albumin content of sputa depends on metabolic products of the tubercle bacillus. [R. F.]

No. 37. SEPTEMBER 10, 1914.

1. *BRENTANO, A. *The Treatment of Gun-shot Wounds of Bones and Joints.*
2. EDITORIAL. *Surgical Experience in the Russo-Japanese War.*
3. CRONER, F. *The Sterilization of Drinking Water in the Field.*
4. HOENE. *An Unusual Case of Bechterew's Disease (Spondylitis Achylopoetica Chronica).*
5. *KROMAYER. *Defects in the Salvarsan Treatment of Syphilis.*
6. ORLOWSKI. *Do Sterile Gonorrheal Shreds Cause Leucorrhoea?*

1. In the field, Brentano has found that infected wounds are of two types. The first is caused by the introduction of an infecting agent at the time the wound is made. The second is caused by organisms which are introduced into the wound during treatment. To avoid the latter infections all wounds at first must be treated as though sterile. Dry aseptic dressings should be applied and such bandages as to make the affected parts as comfortable as possible. If subsequent infection develops, drainage is indicated, and amputation as a final resort. On the whole, the infections which Brentano has seen have been relatively mild. Tetanus and erysipelas were rare, gas bacillus and pyocyanus infections were somewhat commoner, but ordinary pus infections were seen most frequently.

5. Kromayer recalls that until four years ago, mercury was used commonly during the past three centuries in the treatment of syphilis. It has acted quickly and effectively in 90% of the cases treated and has been used over long periods of time without ill effect. Four years ago salvarsan was introduced. Results from its use show that the clinical manifestations of the disease disappear with miraculous speed, and that the general condition of the patient improves under treatment.

Salvarsan has certain disadvantages. It must be given intravenously, which may disturb patients; it is

expensive; and cases of relapse or sudden death may occur during treatment.

Kromayer feels that relapses and accidents occur less often when repeated small doses are given instead of one or two very large doses. A combined mercury and salvarsan cure is the most effective form of treatment. [R. F.]

Obituary.

EDWARD RUSSELL COGSWELL, M.D.

EDWARD RUSSELL COGSWELL, M.D., died at his home in Cambridge, December 22, 1914, aged 73 years. Dr. Cogswell was born at South Berwick, Me., June 1, 1841. He entered Harvard College with the class of 1864, left college in 1862 to serve with the 44th Regiment of Volunteers, Mass. V. M., and was mustered out of the service in June, 1863. He received the degree of M.D. from Harvard in 1867, A.B. as of 1864 in 1871, and A.M. in 1872. He became a Fellow of The Massachusetts Medical Society in 1867 and was transferred to the retired list in 1906.

For eleven years Dr. Cogswell served on the Cambridge School Committee and at the time of his death was president of the Cambridge Savings Bank, a director of the Charles River Trust Company, and a trustee of the Cambridge Hospital.

He is survived by a daughter and by three sons, one of them being also a physician.

Miscellany.

BELGIAN PHYSICIANS' RELIEF FUND.

IN response to an appeal made by Dr. Charles Jacobs of Brussels for aid for civilian physicians, pharmacists and patients in devastated Belgium, a Committee of American Physicians for the aid of the Belgian profession, has been organized. It is composed of the following members:

- Victor C. Vaughan, President American Medical Association.
- William L. Rodman, President-elect American Medical Association.
- John B. Murphy, President Clinical Congress of Surgeons of North America.
- Charles H. Mayo, President-elect Clinical Congress of Surgeons of North America.
- J. M. T. Finney, President American College of Surgeons.
- J. Riddle Goffe, President The Seventh International Congress for Obstetrics and Gynecology.
- George H. Simmons, Editor *Journal of the American Medical Association*.
- Thomas L. Stedman, Editor of the *Medical Record*.

Robert M. Green, Editor of the *Boston Medical and Surgical Journal*.

Claude L. Wheeler, Editor of the *New York Medical Journal*.

Franklin H. Martin, Editor of *Surgery, Gynecology and Obstetrics*.

Howard Canning Taylor, New York, N. Y.

Frank F. Simpson, Pittsburgh, Pa.

The officers of this committee are: Dr. Martin, chairman; Dr. Rodman, vice-chairman; Dr. Simpson, treasurer; and Dr. Taylor, secretary.

The names of other physicians will be added to this later. The executive committee consists of:

Dr. Franklin H. Martin, Chairman, 30 North Michigan Boulevard, Chicago, Ill.

Dr. J. Riddle Goffe, 171 W. 71st Street, New York City.

Dr. Howard Canning Taylor, Secretary, 32 W. 50th Street, New York City.

Dr. Frank F. Simpson, Treasurer, 7048 Jenkins Arcade Building, Pittsburgh, Pa.

Cable inquiries are being made to learn direct from Belgium and Holland the most urgent needs of the profession at this time.

The commission for relief in Belgium will deliver supplies as far as war conditions will permit, and without cost to our committee for transportation and delivery in Belgium. Through the medium of the commission for relief in Belgium efforts are being made to standardize boxes of medical supplies for civilians and to perfect diplomatic arrangements permitting their shipment into Belgium. In order to facilitate delivery it has been arranged that all shipments by the Committee of American Physicians will be made in boxes painted *yellow*. This is in conformity with the color scheme adopted by the commission for relief in Belgium which is designed to facilitate the safe passage of articles across the seas, through the various countries they must traverse and to their ultimate destination.

All subscriptions to the fund for the aid of Belgian physicians should be sent in the form of checks or postal orders and should be made payable to Dr. Frank F. Simpson, treasurer. They should be sent to Dr. Frank F. Simpson, 7048 Jenkins Arcade Building, Pittsburg, Pa.

As many signatures are illegible, all checks should be accompanied by a card giving the donor's name and address in typewriting or printing.

The Union Trust Company of Pittsburg has been selected as the depository of the committee. Checks will be promptly deposited and will at once be available for the purchase of supplies by the Executive Committee.

A weekly report of receipts and expenditures will be made by the Treasurer to the members of the committee and through the medium of the medical journals, to the medical profession as well.

The following is the report of the Treasurer of the Committee of American Physicians for

the relief of the Belgian profession, for the week ending December 26, 1914.

MILITARY NOSTALGIA.

THE issue of the *Lancet* for Nov. 28 presents an interesting editorial account of military nostalgia. The Italians speak familiarly of nostalgia as a disease of recruits, but apparently has not hitherto been recognized as such by the British.

"Nostalgia as a specific disease especially affecting recruits has never figured in English textbooks of medicine or mental disease, but our French allies had up to about the year 1877 issued a whole literature on the subject. Switzerland, as we are informed by Jean Jacques Rousseau, was the original home of what was long regarded as a dangerous malady. The Swiss, asserts, were forbidden to listen to the music of the Ranz-des-Vaches if it happened to be played to them when on the march, since the monotonous strains, associated in their minds with home and the mountains, led to desertions, sickness, and death. Johannes Hofer, a Mulhouse physician, is perhaps the original authority on *mal du pays*, which he calls 'pothopatrialgia.' His book was published in Basle in 1888. He speaks of a specific disease, tells many stories of its extraordinarily fatal results, and ascribes in quaint notation the music of the Ranz-des-Vaches, or Kuh-Reihen, to the sound which he directly traces his 'pothopatrialgia.' As years pass the picturesque element in the sickness becomes modified, and in 1837 we find the subject treated at great length and with complete appearance of scientific justice by Paulinier in a Montpellier thesis. He describes the pallor, taciturnity, absolute dejection, loss of appetite, and so forth, which attack the recruit suffering from home sickness, and adds the curious observation that in the great wars of the

French Republic the illness was unknown owing to the enthusiasm of the soldiers for France, every inch of which had become home in their regard. Later, when the Napoleonic wars had sapped the vitality of the nation, the condition of *mal du pays* became almost epidemic among the boy recruits of 1812 and the following years. There is little to choose between Paulinier's views and those of many of his successors. They all describe much the same set of symptoms. Writing as lately as February, 1863, an American army surgeon, De Witt C. Peters, speaks of the incidence of this form of melancholia among young recruits drawn from the Eastern States of the Union and sent to fight in the, to them, enervating climate of the South. 'The hospitals of New Orleans,' he says, 'during the past summer were filled with such cases. . . The majority of them were young men from the Eastern states, whose love of home and kindred is a characteristic trait.' His definition of the symptoms tallies with that of his predecessors. The symptoms produced by this aberration of mind are, first, great mental dejection, loss of appetite, indifference to external influences, irregular action of the bowels, and slight hectic fever. As the disease progresses it is attended by hysterical weeping, a dull pain in the head, throbbing of the temporal arteries, anxious expression of the face, watchfulness, and increased fever and wasting. Among young prisoners of war it is the worst complication to be encountered, as the writer can truthfully affirm."

Doubtless, as in all functional psychoses, military nostalgia depends largely on the emotional temperament of the race and of the individual.

EXAMINATION FOR ADMISSION TO AMERICAN COLLEGE OF SURGEONS.

At the annual meeting of the American College of Surgeons in Washington, D. C., on November 16, the following report was presented by the committee on examination for admission.

"Your committee begs to submit the following tentative scheme for admission to the American College of Surgeons: On and after November 1, 1914, the candidate for admission to the American College of Surgeons, in addition to fulfilling the conditions previously indicated, i.e. that he shall have been graduated from a medical school for not less than five years, and shall present evidence of personal probity and specialization in surgical lines, shall be required to lay before the committee on examination:

"1. Evidence that applicant has served at least one year as a hospital interne and three years as assistant, or one year as first assistant to a surgeon of recognized ability and with an adequate hospital service. From those who were graduated before 1915 an equivalent surgical experience shall be acceptable, especial im-

portance being attached to laboratory and research work.

"2. Evidence that he has visited other surgical clinics and laboratories than those to which he has been officially appointed, giving the dates of such visits, the time spent, and a brief summary of the work witnessed or performed.

"3. An abstract of at least fifty consecutive major operations which he has himself performed, this abstract to contain the name and address of the doctor or consultant referring the case; the pre-operative diagnosis; the anesthetic given, by whom, the quantity and the time of administration; the date of operation, and a brief description of it, with a note of the time required for its performance, calculated from the first incision to the beginning of the application of the dressing; the post-operative course, and a mention of complications, if such occurred; not only those conditions usually classed as such, but consecutive bleeding which calls for measures directed toward its control, hematoma of sufficient extent to require evacuation or drainage or suppuration, as slight even as a stitch abscess, are to be regarded as complications. The condition on discharge from the hospital with subsequent course of the case up to the date of application for membership, or as near this as is practicable. The applicant shall supplement his individual report of operations by a further abstract report of at least fifty cases in which he has acted as assistant.

"4. All applicants for fellowship to the American College of Surgeons whose date of graduation is 1920 or later shall be graduates from medical schools which shall have demanded of its matriculates two years of collegiate training, or the equivalent, including biology, chemistry, and physics. If the candidate's school of graduation be not accredited by the American College of Surgeons, he shall be required to pass a technical examination.

"5. Surgeons widely recognized by the profession as leaders of progress and exponents of finished technic, by a unanimous vote of the board of regents may be admitted to fellowship on recommendation of the committee on examination."

THE MEDICAL ASSOCIATION OF THE ISTHMIAN CANAL ZONE.

It is the desire of the Medical Association of the Isthmian Canal Zone to be represented at the Panama-Pacific Exposition, to be held in San Francisco during the year 1915.

It was decided at the November meeting of the Society to hold an extraordinary session at the Exposition some time during the Medical Period, which begins June 13 and ends July 3. The most desirable time appears to be the week beginning June 14, 1915, as this date is near the meeting to be held by the American Society of Tropical Medicine and the meeting of the American Medical Association.

It seems appropriate that our Society should be represented, and it is therefore earnestly requested that

all former and present members will endeavor to assemble at San Francisco during that week, and be prepared to support those in charge of the session.

Former members who now live near San Francisco will be asked to take the lead in perfecting the plan and as soon as the temporary chairman can be appointed, the members are requested to get in early communication with him and express their intentions in regard to attendance, and also offer any suggestions in regard to making the extraordinary session a success.

Due notice will be given as soon as the temporary chairman can be named.

H. C. CLARK, *Secretary-Treasurer.*
Ancon, C. Z.

December 16, 1914.

UNITED STATES CIVIL-SERVICE EXAMINATION.

The United States Civil Service Commission announces an open competitive examination for physicians, for men only, on Feb. 3, 1915. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Indian Service at the Hayward School, Wisconsin, at \$1,100 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer or promotion.

Applicants must be graduates of or senior students in recognized medical schools. The names of such senior students will not, however, be entered on the eligible register in the event they pass the examination until they have furnished proof of actual graduation.

Persons who meet the requirements and desire this examination should at once apply for Form 1312, stating the title of the examination for which the form is desired, to the United States Civil Service Commission, Washington, D. C. No application will be accepted unless properly executed, including the medical certificate, and filed with the commission at Washington in time to arrange for the examination at the place selected by the applicant. The county officers' certificate in the application form need not be executed. The exact title of the examination as given at the head of this announcement should be stated in the application form.

APPOINTMENTS.

On Nov. 23 DR. JOSEPH W. COURTNEY, of Boston was appointed, by the Massachusetts State Board of Insanity, examiner of insane prisoners, in place of DR. HENRY STEDMAN, who resigned.

On Dec. 23, DR. THOMAS J. BARRETT, of Worcester Mass., was elected chairman of the Massachusetts State Board of Registration in Dentistry, in place of DR. JOHN F. DOWSEY, who resigned after a service of twenty years.

SOCIETY NOTICE.

The regular mid-winter meeting of the Middlesex South District Medical Society will be held in the Boston Medical Library at noon on Jan. 13, 1915. Dr. John Lovett Morse, of Boston, "Remarks on Infant Feeding and the Disturbances of Digestion in Infancy."

ON OVARIAN TRANSPLANTATION: WITH REPORT OF A CASE OF IMPLANTATION INTO THE UTERUS WITH RESULTING PREGNANCY.*

BY MALCOLM STORER, M.D., BOSTON.

THAT the question of the feasibility and utility of ovarian transplantation is one that has attracted considerable attention in recent years is sufficiently attested by the hundred or more articles on the subject I have looked over, all published since Morris of New York in 1895 reported the first case of successful transplantation in the human. In the same year, working independently, Knauer (*Centrbl. f. Gyn.*, 1896) performed a number of successful experiments upon animals. As the utility of the procedure is evidently still one of the moot points in gynecology, I have been led to prepare this survey of what has thus far been accomplished. The best papers on the subject are those of Martin (*Trans. Am. Gyn. Soc.*, 1911) and Sauvè (*Les greffes ovariennes: Thèse de Paris*, 1910) and it is largely upon their observations that this paper is based.

FEASIBILITY OF TRANSPLANTATION.

The publications of some fifty observers show that ovaries or parts of ovaries can be successfully transplanted in animals from one part of the body to another, especially if autografts are used. In animals these experimentally transplanted ovaries generally live and flourish indefinitely and in many cases the animals have

produced young with regularity (*c. g.* Grigorieff, *Centrbl. f. Gyn.*, 1897, four pregnancies in rabbits).

While in animals autografts are generally successful, the transplantation of ovaries from another animal (heterografts) are apt to be as uniformly unsuccessful. For instance, Knauer had 3 failures in 12 autografts and 12 failures in 13 heterografts. As to what failure or success consists of I think it is fair to regard the experiment as a success clinically if six months after the operation the ovary is still evidently functioning or if conception follows. Of course absolute proof that a graft has taken means that corpora lutea and interstitial cells can be demonstrated microscopically after an interval of say six months. Transplantation of the ovaries from one species to another (rabbit to cat) have been very generally unsuccessful. Occasionally it has been done. Fuges grafted a number of ovaries of monkeys into the spleens of rabbits with occasional successes. So too the grafting of ovaries into males (*c.g.* into the testis) is generally unsuccessful, although Katsch and Schultz have managed to do it.

Naturally the study of the end results of ovarian transplantation in humans is a very different thing from that in animals owing to the difficulty of controlling the experiment with subsequent visual investigation. Even such positive occurrences as a continuation of menstruation and subsequent pregnancies are to be regarded with suspicion unless the reputation of the reporter is such as to give moral certainty that no fragment of ovarian tissue was left behind. This applies of course especially to cases of chronic salpingo-oöphoritis where the many and dense adhesions render at least possible such an accident. Even masters of surgery may easily do this. Lucas Championnière (*Bull. Soc. Chir.*, 1909) relates a case where he removed both

* Read at the Obstetrical Society of Boston, October 27, 1914.

ovaries and menstruation kept up. Next year he opened the abdomen again and removed a piece of ovary that had been left behind. Generally however such pieces are too small and too buried in new adhesions to be found.

It may be said of ovarian grafting in humans that while the chance of the graft taking is distinctly smaller than is the case with animals, still a majority of the autografts do take, while success with heterografts is only exceptional. Even when the transplanted ovary gradually dies, as is often the case, it is a matter of common experience that its function is preserved for at least several months, the menopause being a gradual rather than an abrupt one. From the few histological studies that have been made of grafted ovaries it seems that there is at first almost always a more or less extensive degeneration of the graft, especially of its cortex, due to insufficient blood supply, with often a later regeneration (Preobachensky and Katasch). Of course if this regeneration be a real and permanent one the permanent functional activity of the organ may be expected. Pankow reports careful microscopical examination of a transplanted ovary after several years of menstrual life that showed all the characteristics of a normal ovary.

Technique. Views vary greatly as to the technique of transplantation and as to whether to take the whole ovary or only a part of it. Most men think that it is quite sufficient to stitch a piece of ovary (size generally not stated) to any raw surface and that the vascular anastomosis procedures of Carrel and Guthrie are more or less of a surgical *tour de force* implying a degree of dexterity that is given to few men and that is in fact quite unnecessary. Mauclaire (*Bull. et Men. Soc. Chir. Paris*, 1910) thinking that frequently lack of success is due to poor blood supply and not attaching especial importance to any re-establishment of nervous current claimed necessary by some writers, transplants the ovary into the subcutaneous connecting tissue and establishes a copious blood supply by anastomosing the epigastric artery with one of the ovarian vessels. He has done by various methods 109 autografts, 5 heterografts and 5 cold storage grafts, some of the latter ovaries being several weeks old.

Tuffier, (*Bull. Soc. Chir., Paris*, 1911) who has done some 130 cases, merely slips the ovary into the subcutaneous tissue of the abdominal wall without suture. In his experience with this method the grafts generally live, at first absorbing nutrition by imbibition, though quickly new vessels are formed to supply them. Knauer and Riffert, experimenting on animals, have found these new vessels in four and seven days respectively.

While some men transplant the whole ovary, most experimenters prefer a segment with a cut surface to come into apposition with the raw nourishing surface. Martin, who has probably done more ovarian grafting than any man in

this country, advises grafts not more than $\frac{1}{8}$ inch thick.

The piece of ovary may be grafted anywhere. Tuffier, as I have said, places it in the subcutaneous tissue of the abdominal wall, or as in his later cases, under the sheath of the external oblique, regarding that as affording a condition biologically perfect for the nourishment of the graft, where it will be freely bathed in lymph. Cramer prefers the preperitoneal space beneath the rectus or the subserous tissue of the anterior uterine wall. Kronig and Pankow also prefer the anterior pouch of Douglas. Mauclaire and Marchese like the anterior sheath of the rectus. Dudley Palmer (*Post Graduate*, 1900) sewed a piece of ovary into the uterus, so that it presented in the uterine cavity.

Engel (*Berl. Klin. Wochenschr.*, 1912) implanted a heterograft into the uterine stump of a woman upon whom he had done a double ovariectomy and hysterectomy three years previously. She had been having severe hot flashes and nervous disturbances. Seven weeks later she was having no hot flashes and eventually recovered completely. Of course time and suggestion may have played their parts. Other cases of distinct success with heterografts might be cited. Glass (*N. Y. Med. Jour.*, 1899) transplanted a whole ovary into a woman who two years after a double ovariectomy was suffering from exaggerated symptoms of the menopause. Six days later she had erotic sensations(!), menstruated in 15 days and eight months later was recovered.

Estes (*Penn. Med. Jour.* 1909) in forty cases (humans) implanted the ovary in the site of the tubal insertion, making a wedge shaped pocket in the uterine muscle to receive it, but apparently not opening the uterine cavity. As he says two cases of pregnancy were seen in cases where this procedure was used it is evident that the uterine portion of the tube remained patent.

Uffreduzzi (*Ann. di Obstetrica*, 1911) implanted portions of ovary in the uterine cornua of dogs (20 cases). All showed when killed later at various periods a necrobiosis (degree not stated) and according to him in not a single case were the conditions such that ovulation could have taken place into the uterine cavity nor were in any case any corpora lutea found in the part of the ovary nearest the uterus. This observer seems somewhat of a pessimist, as he makes the further observation that artificial stomata built in clubbed Fallopian tubes will always close up before long, a statement by no means borne out by my personal experience of several pregnancies following the building of such artificial stomata. Anyway Estes' two cases of pregnancy following the implantation of ovarian tissue in the uterine cornua sufficiently discredit Uffreduzzi's statement that uniformly such grafts cannot ovulate into the uterus, in the human at any rate.

Frank (*Centrbl. f. Gyn.*, 1898) was appar-

ently the first to implant ovarian grafts into the uterus or stump of oviduct. Morris and many others have found the broad ligament the best seat for transplantation, while Foa prefers the posterior pouch of Douglas, and Grigorieff and Ribbert the mesentery. For purposes of experimental ovarian tissue has been grafted into the most out-of-the-way places (chiefly, of course, in animals) such as the muscles of the upper thigh (Cramer, Kayser), between the breasts (Brewitt), and into the kidneys, liver, spleen, brain, and doubtless still others. My feeling is that except for the indication of sterility the graft should be placed in a position where it will not be confined so as to allow for a periodic congestion at the menstrual period. Hence I should look askance at transplanting into such places as the abdominal wall and elect for instance the pocket between the insertion of the round ligament and the Fallopian tube. Of course I am not blind to the fact that should anything go wrong with the graft it is conveniently reached if merely in the abdominal wall. There may be something in Lukasevitch's suggestion (*Vratch*, 1901) that it is wise to place the graft as near as possible to its original site. If the tube has been removed Estes' plan of preparing a wedge-shaped bed for it in the cornu appeals to me. Extreme attention to asepsis is absolutely requisite, the graft should be disassociated from the body as short a time as possible and as few sutures should be used as will suffice to anchor the graft in place, and these should be as superficial as may be. Lukasevitch also proposed to transplant a segment of each ovary in case one graft should die.

Pankow (*Zentrbl. f. Gyn.*, 1908) claims that as the ovary consists of two kinds of tissue, the glandular with its internal secretion, and secondly, the follicular apparatus, which generally necroses anyway and in most of the cases operated upon is not needed, the best results will be obtained if it is possible to destroy this glandular tissue while leaving unimpaired the tissue in charge of the internal secretion. Accordingly, in two cases he exposed the ovaries to be transplanted to a moderately soft Roentgen tube at 25 cm. for ten minutes and then transplanted them. The importance of this procedure is still very much *sub judice*.

One other matter connected with technic is the necessity of exercising the greatest care as to the donor in the case of heterografts. I can well imagine that a suit for malpractice would stand should the donor prove to be a syphilitic. Most of the men who have used heterografts in recent years have availed themselves of the Wassermann reaction.

Internal Secretion. While exact knowledge of the qualities and influence of the much discussed ovarian secretion is still sadly wanting, enough is known about it since Fraenkel's paper in 1913 to warrant the statement that it exerts a profound influence upon the female economy and that after functional ovarian death at the

menopause, rightly called the grand climacteric, a woman's physiological life undergoes great modification. The careful researches of Limon and Branca seem to prove that while the cortical portion of the ovary is concerned chiefly with childbearing there is secreted from its interstitial cells a something which, to quote Sauvé, aids in the development of the skeleton, for according to him castrated women are smaller than non-castrated, has influence on the circulating system, increasing the bulk of blood and its degree of hemoglobin, is a powerful controller of the nervous system, works upon various secretions, and has such influence upon the activity of the kidneys (phosphaturia diminishing after removal of ovaries) that by simply measuring the amount of phosphates eliminated Jandy professes to be able to tell whether an ovarian graft has taken or not. Whether or no the ovarian secretion possesses quite such far-reaching qualities it certainly has its great importance, and most men agree that total removal of the ovaries, especially in very young women is followed in many cases by the train of symptoms grouped under the term postoperative or premature menopause, of which gradual atrophy of the genitals and marked increase of fat are the chief signs and marked nervous phenomena the chief symptoms. In other words, the phenomena characteristic of the natural menopause are apt to be compressed into a few months instead of being spread out over a number of years. I know many men are fortunate enough to have no reason to attach much importance to the premature menopause and say their patients never have any trouble to amount to anything. I may have been unfortunate, but I have seen many such cases, suffering to a degree that is very seldom seen in connection with the natural menopause. Looking over the literature, I am rather struck by the fact that the general surgeon, concerned chiefly with the immediate outcome of his operation, sees but little of the premature menopause, while the gynecologist, who is apt to have opportunities for more careful after-study of his cases sees comparatively very many of them. I do not deny that a great deal of nonsense has been written about the premature menopause and many nervous symptoms referred to castration, where probably the presence or absence of the ovaries had but little to do with the matter, except perhaps by suggestion; but on the other hand a sufficiency of cases have made most of us very loath to sacrifice both ovaries, especially in young women. In certain cases, however, for one reason or another, it seems inadvisable to leave either ovary *in situ*, and it is in these cases that ovarian transplantation has chiefly been done, in the hope that thereby the troubles grouped under the term premature menopause would be avoided. It is somewhat hard to draw a conclusion as to how far this hope has been justified. In the first place, there can be little doubt but that in many of the cases in which transplantation was per-

formed at least one ovary or part of one might perfectly well have been left in its original place and that the operation was unnecessary. I notice French surgeons seem to hesitate to leave healthy ovaries. One writer of repute says that the ovaries must be removed in every case of bilateral salpingo-ovaritis and with every uterine tumor of any size. In removing tubes, I have often left the ovaries and hardly ever remove them in hysterectomies or myomectomies in young women. In these uncalled for transplantations, as a good many ovarian grafts die, we have a large series of cases of ovarian insufficiency which would not have existed had transplantation not been done, which, of course, vitiates statistics. On the other hand, while enthusiasts report cases of profound nervous symptoms, lasting for months and even years, disappearing promptly after a successful grafting, and in a few cases even reestablishment of the long absent menstrual function, other men of experience feel that any good effect from a graft is so problematical that it is not worth doing. This question of the menstrual function after grafts shows the dangers of statistics. A distinguished French opponent of ovarian transplantation states that as menstruation continues in, at most, 17% of the cases of grafting and also continues in some 20% of cases of double ovariectomy anyway, the grafting is of little use. Now I doubt very much that it is the experience of American gynecologists that menstruation continues in 20% of their double ovariectomies. In my limited experience 1 or 2% would be a much truer figure. Of course most of these cases mean that a piece of ovary was left. I remember years ago, when bilateral ovariectomy was more common, Dr. Whitney told me that it was a common experience to find cut surfaces on examining such ovaries. In other cases of menstruation continuing after the removal of ovarian cysts, the cyst may very well have been parovarian and not recognized as such. The truth of the matter as far as grafting for the avoidance of the premature menopause is concerned seems to be about as follows: While in the long run it is very unsatisfactory and transplanted ovaries generally die after a year or so, they are apt to remain alive and functioning for about that time and so allow nature to accommodate itself to the changed conditions slowly instead of being forced to readjust itself precipitously. If, then, it is necessary for any reason to remove both ovaries in a young woman, and they are healthy as far as can be seen, there is a certain justification of grafting a portion of one ovary, preferably as near its original site as possible. To be sure, there will very likely be certain inconveniences and discomforts caused by the transplanted ovary, but their sum will generally amount to comparatively little as contrasted with the sum of the discomforts of a well marked case of premature menopause. Such discomforts will be those to be expected from the periodical swelling of an organ more or less

confined, if the ovary is slipped under the sheath of the external oblique, for example. Then also such ovaries as they atrophy may cause trouble, as in my own case. Other bad results mentioned are dysmenorrhea (Morris, Martin), vesical troubles (Pankow), thrombophlebitis (Morris), results due partly to the seat of transplantation and partly to extrinsic causes. But as I say, the sum of such bad results seems small in comparison with the probable gain. Thus in 59 reported autografts, 15 cases may be said to have had permanent good health follow, *i.e.* normal menstruation kept up, while most of the failures did not impress me as being much worse than they would have anyway. Of 14 heterografts only four could be regarded as successful and that only questionably. It is sufficient only to mention some of the indications for which ovarian grafting has been tried, such as menorrhagia, amenorrhea, osteomalacia, sexual frigidity, nymphomania, and chlorosis. I have little sympathy with such operative experimentation.

There is, however, one indication for ovarian transplantation which seems to me thoroughly justifiable. I refer to operations done with the hope of pregnancy ensuing.

The problem presents itself under two aspects: Where a woman still has one or both ovaries left and it is a question of rendering it possible for ova to find their way into the uterine cavity, and where it is a question of transplanting an ovary from another woman. In this latter class the utility of heterografts is a questionable one. As Martin says, there is a very distinct antagonism of the blood and tissues of one individual to those of another, while there is practically no such antagonism between the blood and tissues of an individual to grafts from her own ovary. Results of heterografting are in the main very disappointing, even as regards menstruation, but Martin believes that they would be more satisfactory if the grafting were done sooner after the original loss of the ovaries, before the patient has lost the habit of menstruating, so to say. In one case of heterografting he had, however, menstruation start up and continue some months after a year's abeyance. The problem further arises in the very unlikely event of a living child being the result of a heterograft that there may be some difficulty in saying just whose child it is. This may be only an academic question, but that it is a real one was shown by a somewhat acrimonious discussion at the Edinboro Medical Society when such a case was reported. While the child would of course theoretically be the offspring of the donor of the ovary, I think most women would be content to feel that if they had given birth to it they were justified in regarding it as their child. Interesting questions of heredity naturally might arise. There have been reported three cases of living children born as the result of heterografting and three or four pregnancies resulting in miscarriages. Of course I admit that in these cases we

must always face the suspicion that a tiny piece of the original ovary was left behind. Sauvé rather ungenerously remarks that pregnancies following heterografts should be viewed with suspicion as most of them come from the country, where in some thirty published cases pregnancy has followed "castration" without grafts. When, however, there has been a post-operative amenorrhea for a year or two, and then after a heterograft menstruation followed by conception has occurred the case seems proven.

A dozen or more cases of pregnancy following autografts, however, seem to justify the operation, in spite of most of them having miscarried. The problem may present itself in two ways. In the contingency of its being necessary to remove the ovaries in a case in which the tubes are patent it is a very simple thing to graft a portion of the ovary near the orifice of the tube or to do so in cases where it is necessary to amputate more or less of the tube. In cases, however, where the tube has been removed well into the uterine cornu the problem is a more complicated one and it is a case of this latter category that I shall report tonight.

I reported the following case briefly in this society some years ago, but have not published it. The procedure I followed was original as far as I then knew, as I had not heard of the somewhat similar operations by Frank in 1898 and Dudley in 1900.

F. D. was first seen April, 1904. She was a strong woman of 24. She had had both tubes and the left ovary removed by Dr. Beach three years previously for an acute gonorrheal salpingitis of a month's duration. A month later no gonococci were to be found and when I saw her she had been menstruating normally and was in perfect health, with no evidence of gonorrhea. Matrimony was now contemplated but it was contingent upon its being at least possible for her to become pregnant. She had, by the way, occasional slight pains in the region of the appendix and right ovary, which was fixed and prolapsed. Understanding fully the probability of nonsuccess she demanded an operation.

April 12, 1904, assisted by Dr. C. O. Kepler, I found the omentum and the intestines densely adherent to the old scar and bladder and fundus. In breaking them up the outer intestinal wall was injured in two places and overcast with catgut. The remaining right ovary was freed with much difficulty and proved to be a pretty poor one, being riddled with cysts, especially in its right half. The tubal stumps were about half an inch long. The right tubal stump was divided downwards until the uterine cavity was laid well open. The ovary was then bisected from above downwards, carrying the incision well down into the broad ligament, so that each half of the ovary retained at least some of its original blood supply. The cut surface of the distal half was then closed with catgut, leaving that half to function in case the other half died. The proximal segment of the ovary was then introduced into the cut in the uterine wall and lightly anchored in place with fine catgut, in such a way that most of its cortex projected into the uterine cavity. The uterine wall was then brought to-

gether over it and its pedicle, in which there was a fairly good sized artery, with deep and superficial layers of catgut. The pedicle was sufficiently long not to pull the fundus over to the right at all. A chronic appendix was then removed.

Six days later a pelvic abscess was drained by the vagina. A month after the operation she menstruated in perfect comfort, more so than for three years.

I saw her again in January, 1905. She had been menstruating regularly but for the last few months with increasing pain, and finding a mass to the right of the uterus I opened her again and removed a shell representing the degenerated remnants of the piece of ovary I left *in situ* and a peritoneal cyst the size of a child's fist. I examined the seat of the transplanted ovary with much care but could find nothing abnormal nor any trace of its pedicle, which may have been lost in the many adhesions present. At the same time a small ventral hernia was closed. She made a good recovery but did not menstruate for four months. She was then put on various emmenagogues and on May 25 flowed for one day. In June, July and August she flowed normally and evidently the transplanted ovary was working perfectly. She was unwell Aug. 1 and on Nov. 4 I received a letter from her attending physician from which I quote. "She now comes to me with symptoms of pregnancy and examination shows an enlargement of the uterus, bluish appearance of the cervix and labia. She has considerable nausea and has noticed an enlargement of the waist." A letter from the patient makes the diagnosis of pregnancy even more definite, so much so that one of the best obstetricians in America was engaged to attend at her confinement. My correspondent also speaks of a mass on the left side of the uterus "which worries him a little." "This mass is nodular with rather dense adhesions about it, yet it is not tender and she runs no temperature." This putative pregnancy was sixteen months after the transplantation. Everything went as should a normal pregnancy till Dec. 12, three and a half months after the last menstruation, when she passed with some hemorrhage a mass of detritus and the uterus rapidly decreased in size. In view of the physician's report and what took place it seems fair to regard this as the abortion of an early pregnancy, retained for some time after the death of the fetus. In January she flowed and continued to do so but with increasing irregularity and nervous disturbances. About this time another surgeon removed some more peritoneal cysts, the mass to the left of the uterus my correspondent had spoken of.

Menstruation stopped entirely February, 1909 and I saw her in May. She was then the picture of health but a nervous wreck and her life a torment with hot flashes, eye ache and other symptoms of the premature menopause. She was now twenty-six. After she had been on corpora lutea for a time with little or no benefit, I advised a hysterectomy, in spite of her urging me strongly to transplant another portion of ovary from another woman, for she was by no means discouraged. Hysterectomy was done in February, 1911 in a western city and I understand she died thirty-six hours later of streptococcal infection.

If this case was pregnant as seems probable, and she had not aborted, the interesting question arises as to what would have been the course of labor. It would also seem to bring out that the tube plays

merely an accidental part in conception if, as seems agreed, conception usually takes place in it. While the untoward final result in this case is to be deplored, I confess to a desire to further experimentation.

A STUDY OF THE EPILEPSY OF DOSTOJEWSKY.*

BY L. PIERCE CLARK, M.D., NEW YORK.

FOR some time past I have been interested in a study of the psychogenic factors of epilepsy. First I made an intensive research of the everyday personality of the epileptic before the convulsive part of his malady had developed. The material consisted of about twenty-five cases carefully collected and controlled. As the result of that study I found there was a fairly definite type of makeup.¹ From the viewpoint of that study I undertook to analyze many of the individual cases still more in detail; I found that the essential defect in the epileptic makeup was in the affective sphere of the mind; there existed an emotional infantilism due to a defect in development of the psychosexual life. I was further able, by dream analysis and by close study of the minor, and in some instances of the major attacks, to detect an analogous striving of the unconscious in the fit not unlike that of the dream, the two states not only frequently corresponded in content but were often reciprocative. In other words, the epileptic attack was a libidinous satisfaction to the epileptic individual and the fit possessed a varied yet thinly disguised sexual content of the dream, only the former was much more intense and complete and therefore not so often recoverable in memory content after the attack had passed. It was not only a wish but a fulfillment. It was also found both in the dream and in the analyzable epileptic episodes (composed of psychic and minor fits mostly) that the libidinous strivings were simple and infantile. Viewed in this light the settings of the fit led one to believe the epileptic attack was an unconscious desire to return to the state of the libido comparable or identical with that of intra metroerotism. This and many other interesting facts were brought out. While the study was in progress it occurred to me to see how many great persons in history may have shown their disease in such a manner as to support this theory. Obviously many historical inaccuracies will creep in to the published accounts of such individuals, but inasmuch as many writers have made a precise and detailed analysis of such, the study will not be without interest.

I shall undertake to give a brief sketch of some of the salient points in the epi-

lepsy of the late Russian novelist, Dostojewsky, who was long a sufferer from the malady. I have been obliged to depend largely upon translations made for me from the Russian literature and on the admirable essay of the subject by Segaloff, whose work appeared several years ago in Munich. Doubtless many have already read this work, but for those who have not, these notes may be of some interest. Segaloff's treatment of the subject is in many respects so excellent an illustration of my theory of the mechanism of epilepsy and its essential contentions of this malady that I shall offer no apologies for commenting upon it at this time. The main tenets of my thesis but briefly outlined in its main arguments and conclusions I here present as a sort of preface sketch to this dissertation.

Dostojewsky's romances abound in psychopathic characters. Russian alienists long marvelled at his expert knowledge of psychopathology, which he evidently obtained from self study. Even in early childhood he had hallucinations and it is generally known that he was epileptic.

Strakoff's recollections of him state that all which Dostojewsky wrote had been lived through by him with fervor and devotion. Dostojewsky was one of the most subjective of authors, whose novel characters were created from his own. His gloomy moods appeared in his works.

As a rule Dostojewsky had convulsions monthly, sometimes, however, twice a week. When he lived abroad, in a milder climate and was spared from sources of excitement, his attacks were much less frequent—up to intervals of four months intervened. There were always prodromal feelings before attacks although at times even he was deceived. Strakoff was present at an attack in 1865. The novelist visited him toward 11 p. m. and a lively conversation was soon in progress. The subject is not recalled, but it was an abstract one and weighty. Dostojewsky became enthusiastic and paced the floor. In enraptured tones he spoke of things sublime. As Strakoff made a remark of approval, the novelist turned his inspired face full upon him, and his exalted excitement was readily seen. Dostojewsky paused for a moment as if in search of a word, with open mouth, but no utterance followed. Strakoff felt that something was about to happen. Suddenly from his open mouth came a peculiar, prolonged and meaningless cry and Dostojewsky fell senseless to the floor. The attack was not a violent one but he had convulsions and foamed at the mouth.

Dostojewsky told Strakoff that he always had a feeling of ecstasy before these attacks. His sensations of happiness were so intense that no normal mind could experience them. He said his feelings were in complete harmony with the world, and for a few seconds of them one would give ten years of his life. The attacks sometimes caused slight injuries, and the convulsions were followed by muscular pains. There was often a temporary failure of memory and for

* Read in abstract before New York Neurological Society, Dec. 1, 1914.

¹ A Personality Study of the Epileptic Constitution, Amer. Jour. Med. Sci., Nov., 1914, No. 5.

two or three days he felt quite prostrated, and very melancholy. He was possessed by a certain anguish and irritability which could hardly be mastered. He felt himself a criminal guilty of some offense unknown to him. One of his characters in "The Karamasoff Brothers" suffers in the same way and for the same reason. Milukoff, another who knew him, speaks of certain alleged peculiarities of Dostojewsky, such as avoiding acquaintances on the street, refusing to acknowledge greetings in society (he even would ask, "who is that man," when greeted by some friend). Milukoff admits that such things may have occurred, but is certain that if Dostojewsky behaved in that manner it was after an attack. Dostojewsky had once taken tea at Milukoff's house, and just as a glass was handed to him he turned pale, began to totter and as soon as he was led to a sofa he had a fit. Fifteen minutes later he asked what had befallen him. When told he should stay all night he refused decidedly, saying he must go home, but couldn't or wouldn't give a reason for going. He even refused a carriage to the station, saying he needed the walk. His host nevertheless went along. As they were passing through a park Dostojewsky came to a halt and whispered that he felt an attack coming on. He was led to a bench but no attack appeared. There were two similar false alarms before Dostojewsky reached the station where a relative was found who took the train with him. Next day Milukoff visited Dostojewsky at his home. The latter was very weak and did not at first recognize Milukoff.

It appears from Solowjew that Dostojewsky had his first attack while in exile and was never afterwards free. He remembered down to the finest details everything which happened to him before the disease appeared,—every event in his life, every face, everything which he had ever read or heard. But of that which happened after the first attack, much has been forgotten. He often completely forgot those who had been well known to him. He even forgot much that he himself wrote. In writing his romance, "The Devil," the contents of the book were forgotten and he often had to reread the preceding chapters before he could go ahead with the story.

Solowjew states that after a crisis Dostojewsky was often insufferable. His nervous state was so marked that he was quite irresponsible. He often came in the room like a black cloud, forgot to greet people and sought opportunities to quarrel. It appeared to Dostojewsky that everything which was said to him was vexing, insulting, or it was done to excite him. The conversation had to be brought to his pet subjects about which Dostojewsky would then become enthused. After an hour of such gentle treatment Dostojewsky would be in the best humor. Only his pallor, brilliant eyes and heavy breathing showed that he was mentally disturbed. Such changes of mood are often found in Dostojewsky's books

In the youthful recollections of Sonia Kowalewsky she says that she and her sister knew of Dostojewsky's disease, but never dared to speak to him of it. He himself once introduced the subject and told how the first attack came about. It was something as follows: While in exile he had been punished in the house of correction. He was isolated from his fellow beings and could exchange ideas with no rational person. Suddenly an old friend visited him, on an Easter night. Forgetting the sacredness of the occasion, both began to converse on literature, art, philosophy and religion, during which hours passed. The friend was an atheist while Dostojewsky was a believer in Christ and immortality, and an argument started. Dostojewsky became greatly excited. It was now early morning and the bells began to call the faithful to arise. Dostojewsky felt a sense of ecstasy, thought he was in Paradise (as was also Mohammed, another epileptic). During this ecstasy the first attack appeared.

While he spoke thus to the sisters, his mouth failed to articulate, his facial muscles twitched, he evidently saw the fear and anxiety in the girls' faces, they feared that an attack was due. He smiled and told them not to be afraid as he always knew when an attack was pending. However, he told them later that he had had an attack at the time.

From the preceding testimony there can be no doubt that Dostojewsky had epileptic attacks. In the first attack the sound of church bells was an auditory aura. Dostojewsky admitted afterward that no bells really rang. The unspeakably ecstatic feeling was associated with nearness to Heaven or Paradise.

For two or three days after the attack Dostojewsky was in the twilight state. The morose nature and great irritability showed the extraordinary action of the disease upon him. He wrote "The Devil" when his disease was beginning to tell on him, as was plainly evident in the character of the book. The circumstantial, detailed treatment is characteristic of the epileptic activity, and as a result the work lacks in cohesiveness. Malice and intolerance are also shown to a remarkable degree.

The preceding covers the period of 1860 to 1880. It should be added that Dostojewsky had a mania for roulette. In 1863 he started on a tour but lost all his money in this way, and this happened more than once. During this period the attacks were unusually frequent, and he was doubtless insane as a result. He had a fixed belief that he would win and once was 4,000 francs ahead and not playing. His wife begged him to be satisfied, but as he had sometimes been 30,000 francs ahead while playing, this was impossible. He lost everything, even his own and his wife's personal belongings. How infantile, foolish or defective this may have been I shall leave others to judge. The indictment is only so strong as one is inclined to personally make it.

As far as known Dostojewsky was very temperate in both eating and drinking. He was fond of sweets, was a heavy smoker and consumed much tea and coffee. But little is known of any affairs with women. As already stated, he was married. He was born in Moscow in 1823 and was the son of a physician. Their circumstances in life were moderate and Dostojewsky led a life confined in small compass. Not much is known of his childhood. The mother was sickly and died of consumption in 1836, so young that Dostojewsky was raised partly by nurses who told him gruesome stories. He was very impressionable and imitative, and was on the lookout for the novel. The father undertook the boy's education. He was a stern man, a military physician, and was a stickler for discipline.

In 1831 the boy moved to the country and there plunged into rural life, developing a love for nature, and became absorbed in folklore from peasants. He was much given to reverie. As a reader he was precocious and he limited himself to literature proper. He was a great admirer of Pushkin, whose death in a duel occurred near that of his mother's. These deaths gave him a great shock. It is authentically reported that he lost his voice, probably a psychogenic episode.

In 1837, when Dostojewsky was nearly fifteen, he entered the School of Engineering at Petersburg and remained four years there, but found the discipline very severe. He developed tuberculous symptoms which would seem to have been little more than scrofulous glands. His cough may have been due to excessive smoking. He remained an engineer only until 1844, when he at once devoted himself to his first novel, "Poor Folks." Soon afterwards he became a member of a literary coterie to which belonged Tolstoi and other to-be-famous men. His novels were very successful and he was a prolific writer.

Long before his first epileptic attack he was the victim of so-called neurasthenia or some hypochondria. An alarming symptom was a lethargic sleep. A state of depression coupled with anxiety about the future troubled him. At times he lived in a dream for long periods. Yet in 1849, when he had trouble with the Government, all his mental symptoms left him and he began to show admirable qualities; he exhibited patience, tranquillity, etc. He believed that his arrest saved his reason. Evidently his numerous nervous and mental symptoms were all psychogenic. His lethargic sleeps, however suggest that he was already on the way to an epileptic career. One medical man who treated him before his exile pronounced him of the epileptic temperament, and said that some of his disturbed episodes were so severe that his mental integrity was threatened.

In Dostojewsky's works we find no less than five types of epileptics. In "The Landlady," written in 1874, before he had developed his full

talent, is a character named Murin, an old man, in whom we see the "epileptic character" without any effort. He has the moods of Dostojewsky when the latter was young. The attacks described, however, are crude, as any layman might view them. The influence of alcohol on epilepsy is shown, Murin has a seizure after drinking a glass of wine.

The second type is represented by "Nelly" in a work written in 1861 after Dostojewsky had been banished and had had time to study his own case. The influence of heredity is shown in this work. The grandfather (maternal?) was "odd." The mother was exalted, readily excited and inclined to reveries. Her stubbornness in holding certain ethical views was readily mistaken for a strong will. The child's life was miserable and became worse after the mother's death. She was of pronounced epileptic character. Her attacks are described as follows: "After a prolonged stare (at some person) she gave a fearful cry, her face was distorted, and she fell to the floor. After the convulsions she looked fixedly at the same person as if trying to collect her thoughts. At last her face lighted up as she began to comprehend. For a long time she could not collect her thoughts and murmured meaningless words. For a long time she did not fully regain her senses. Reality was much mixed with fancies, and it seemed that something fearful excited her soul. Finally she fell into a deep sleep. She was pale and her lips were still bleeding. Her face, despite the sleep, showed great fear and a painful longing. Once when Nelly was requested by the physician to take medicine, she spat it out three times in succession in his face. Astonished at his good nature she began to sob in despair." In this work we see excitability, moodiness, sensitiveness, suspicion, want of psychic balance and endless oscillation between exaltation and apathy.

The third type is seen in "The Idiot" (1868). The boy had had attacks since earliest childhood. Sent to Switzerland for treatment he improved so much under expert care that he figures in the story as a well developed human being. His appearance betrayed nothing. His eyes were large and blue with a leaden color of the iris and a fixed look which to some suggested epilepsy. There was in him something silent and melancholy. Describing his attacks in childhood he said that after a series of violent seizures he was left apathetic, without recollection. His brain worked, but not logically. He could not connect more than two or three ideas. As the attacks became weaker, his condition improved correspondingly. An inexpressible longing possessed him. Often he wished to weep. He marvelled at everything, was excited over everything. It depressed him very much because all about him was strange. This epileptic, the Count Mischkin, is a good man, and has fine feelings. Abnormal only is his naiveté, which often borders on stupidity. His will is

weak, so that it lends him something boyish and immature. Like Dostojewsky himself, he writes a beautiful hand.

Associated with Mischkin are accounts of the twilight state which are of great value to the psychiatrist; also the feelings and thoughts of an epileptic in his "sound" movements; thus, to quote Dostojewsky's text, "At times he looked about him with great curiosity, but most frequently was quite indifferent, not even knowing where he himself was going. He lived in painful excitement and restlessness, wishing to be alone, yet finding solitude unbearable. Presently he finds himself occupied with something, a former employment. He has been so occupied for a long time but has not known it. He begins to seek something but at once forgets it. After half an hour he resumes the search restlessly. He knew that before his attacks he is distracted, often confusing objects and faces and requiring all his efforts to prevent blunders. It was necessary to give his full attention for a long time to everything he saw. In his epileptic states there would suddenly be a clearing up of consciousness, when his mind would glow and all his old powers return. The sensation of living, of self consciousness, would be accentuated tenfold. These periods, however, lasted but an instant. During their existence all excitement, doubt, restlessness vanished suddenly, replaced by full harmony, joy and hope. These bright moments, however, really presaged convulsive attacks and therefore were unendurable. He looked back on them, however, as glimpses of a higher existence but nevertheless pathological. This was the paradox of his disease. There could be no doubt of the beauty of these moments. They were not like the sensations due to alcohol or opium. One such experience compensated for all the evil of the disease and was worth a whole lifetime. In such moments he felt that some day time would cease to exist." Thus one catches a flavor also of Dostojewsky's style of treatment of his characters. Continuing one reads, "No doubt Mohammed's religious faith was based on these experiences, thought Mischkin. He had similar moments. The soul was flooded with a wonderful inner light. Yet the time required was but half a second! This moment passed at once into the cry of an epileptic seizure. Everything human has vanished for the time. The voice which is heard is not human. In one attack Mischkin falls down a stone stairway. Once when in company Mischkin was excitedly discussing a subject. Gradually a feeling of infinite happiness came over him. He ceased speaking save to answer questions and at last became completely silent. He sat quietly and listened, and seemed to sink in happiness. A sublime inspiration filled him more and more, and he was ready at any moment to 'burst into flame.' Then he began to declaim with passion, strove for breath, was as if suffocated with the excess of goodness in his heart. He ceased to breathe, became pale,

seated himself and began to look about, regardless, with flaming eyes. His word storm, in which one thought followed so quickly upon another, forboded some danger, and in fact he shattered a vase. When this was past he felt himself struck to the heart, filled with mystic horror. Another instant and this gave way to a feeling of light, joy and inspiration. Then he began to breathe again, taking deep breaths. The expected severe attack had not taken place. For a long time he remained confused. He beheld and understood what was going on but seemed to himself to be only an unseen onlooker, taking no part in anything. Then once more he began to declaim. He spoke with increasing inspiration, saying things he did not intend. Another period of full ecstasy followed and then the attack came. After a series of strong psychic disturbances, minor attacks and psychic episodes his reason began to darken." At the end of the story we find him in a Swiss institute hopelessly demented.

The fourth type of epileptic is Kiriloff in "The Devil" (1871-2). To quote text from Dostojewsky's novel, "Externally he presented nothing singular but his speech is striking. He speaks in monosyllables or broken sentences and one notices at once that his thinking is difficult. His ideas are associated in the strangest fashion. His contemplations are religious-mystic, which are rooted in his illusions and hallucinations. He has no convulsions but psychic equivalents. He says of these, 'For seconds, not over five or six in all, in which there is a sudden feeling of infinite harmony which fills the whole of existence.' This feeling is not earthly nor is it necessarily heavenly. But an earthly being cannot tolerate it, and must be physically transformed or perish. It is as if one suddenly felt within him the whole of Nature and said, 'Yes, this is Truth.' So the Creator might have spoken as he finished the world. Here is no commotion, only simple joy. The feeling is not only that, but something higher. Terrible it is that these feelings are so clear, this joy so powerful. If this mood should last over five seconds the soul could not endure it and must perish. During these few seconds one lives through an entire life. Of what need is posterity, when the entire goal of life has been attained." We find that Kiriloff has one or two of these experiences weekly, and they never usher in severe attacks. He was told that they would do so eventually. Mohammed flew through the entire heavens before the water could flow from a can. It required five seconds to empty the can, and for Mohammed to have an epileptic fit.

In "The Karamasoff Brothers" (1879-80) we find Smerdjakoff, a classical epileptic. His mother, an idiot, wandered about clad only in a chemise. His father was a debauche. The boy was born in a truck garden and he was raised by the brothers. At 21 he was shy and silent. He was, however, high spirited and apparently despised all mankind. In his childhood he killed

eats and buried them with pomp. Once when whipped he crawled into a corner where for a week he looked vexedly at all people. Once he took a box on the ear calmly but afterwards went into a corner as before. After a similar experience he had his first convulsion and they continued throughout his life, both mild and severe in type. In time he came to despise food. He would toy with a mouthful for a long time, finally deciding to eat it. After several years of instruction he changed greatly, aged rapidly, was pale and wrinkled and had the look of a eunuch. Visiting Moscow he took but little interest in it but learned to appreciate good clothes and clean linen. He became an excellent cook and his other interests were clothing, pomades, perfumery, etc. Men and women he despised alike.

Finally Smerdjakoff had a trick of gazing on the ground for some minutes. Walking along he would suddenly stop, lower his head and stare downward for ten minutes. Whether he simply stared or was fixed by something in his own mind puzzled those who saw him. Dostojewsky says in the text, "These people are not uncommon. It is probable that he was collecting certain impressions. As a result at some remote period an epileptic might begin a voyage, burn a house, etc." However, one of the brothers upon questioning him found always a deep pathological self love.

What are the special points brought out in this cursory study of Dostojewsky, especially in the light of our present day knowledge of epilepsy? First, that he had the infantile type of mentality. He reckoned or dated all things from his own inner consciousness. He was intensely egoistic, most of his reported conversations were but monologues on his part. Still earlier he was intensively devoted to his mother; had a psychogenic or hysterical episode after her death; had an intense antagonism to his father who was a stern disciplinarian and from whom he revolted to his tutors who fed him upon the gruesome tales his fancy craved. He could not take on or submit to the onerous discipline in the engineering school and left it with a thorough distaste for it owing to the strictness of the discipline. He continued to develop his self-centered characteristics, failed to observe the conventions of society, did not recognize friends in these fits of abstraction. He inconvenienced his friends by requiring the household arrangements to be changed to suit his own convenience. He had childish tantrums and odd ways of defying the physician's prescriptions of foods. Quite some time before his epilepsy developed his personality underwent further changes, he had fits of depression and anxiety, lethargic sleep after which he seemed to strive to continue his life in a dream. He also had periods of extreme irritability, embittered himself with governmental authority and suffered in lonely exile. Here in the light of recent psychoanalytic research, one notes with interest that after a revolt

against the government, which is unconsciously the adult father, Dostojewsky at once lost the neurasthenic and hypochondriacal symptoms and became patient, tranquil, etc. Dostojewsky himself believes his mental integrity was saved by this action on his part. To an intense egoistic nature who suffers intensely under the chafing restrictions of the paternal rule the revolt against such authority often permits a freer range of the libido and the repressive symptoms before such an act of revolt often disappear completely. One cannot, however, be quite clear how much of the suppression of the libido was relieved, as it seems Dostojewsky's epilepsy also showed about this time, although in a somewhat masked form. He was definitely epileptic soon after he took up his life in exile, perhaps the attacks carried off much of the pent up repression of the libido as has been noted in many another epileptic. Often migraine attacks, lethargies and abstractions are to be found in the preconvulsive stage of an after frankly diagnosable epileptic.

The account of the first genuine attack, much of which was to recur in subsequent seizures, is characteristic. One should note especially, after long confinement, the expansion of the ego, possibly the inflation of the infantile unconscious in the term of Hoch; the meeting with an old friend; the religious controversy; the insistence of Dostojewsky in establishing the orthodox tenets of a paradise in the hereafter; the aura, and the inflation of the unconscious at the beginning of an attack. Again the feeling of oneness with truth and the eternal verities of the universe in the attack, and then Dostojewsky was in ecstacy of a minor attack. The expansion of his ego at the beginning of an attack (the sense of *allmacht*) the oneness with the peace, security and safety of paradise itself, strongly suggest the unconscious strivings to revive the infantile memories of the mother life and its paradoxical qualities. Regarding the latter, I hope at another time soon to dilate with greater emphasis in a comparative study of the epilepsies of St. Paul, Plutarch, Mother Ann Lee, Mohammed and even Joseph Smith, the latter of whom, as is not frequently known, died epileptic. In time it will probably seem less strange that much of our religious conception of Heaven which has been fashioned by epileptics out of their unconscious conceptions of the mother life should be so satisfying to the entire human family.

All of the outcroppings of Dostojewsky's egoistic and infantile feelings and ideas in the minor attacks and in the beginnings of the major attacks are over and over again elaborated in Dostojewsky's novels as we have seen. Lest too much stress be placed upon the epileptic's own responsibility and his shortcomings for his disease Dostojewsky now and then accounts for the epilepsy in many of his novel characters by family heredity from which his creations sprang.

We see in Dostojewsky's personality the dis-

organization of the mind, the replacement of bad judgment, faulty memory and childish reversions in character as the result of indulgences in his disease. The same is also portrayed in all his novel characters. Dostojewsky also mentions how his characters all mend when the individuals grow better of their disease. Yet the persistence of the naiveté, the weak and vacillating will, the boyishness and immaturity of Count Mischkin's mind under a partial restoration from his disease shows Dostojewsky's unconscious but deep appreciation of the infantile make-up of the epileptic constitution and probably of his own character as well.

Finally, it is interesting to note the probable unconscious workings in Dostojewsky's mind when he wrote "The Devil;" no psychoanalyst needs to be told that the devil is the father symbol in a derogatory sense. Dostojewsky often forgot the thread of the narrative in this story and had to reread much of the manuscript to finish the succeeding chapters. In it all lies a virile hate which Dostojewsky cannot repress or seems to make little effort to do so. It even goes far to mar an otherwise admirable piece of writing. The malice, hatred and intolerance shown in this novel is much more than the situation would ordinarily seem to demand. Dostojewsky told one friend that he so hated the book and its subject he could never reread it once it had been written.

OCCUPATIONAL DISEASE AND THE PUBLIC HEALTH.*

BY DONALD B. ARMSTRONG, M.D., NEW YORK,

Director of the Department of Social Welfare, New York Association for Improving the Condition of the Poor.

RHODE ISLAND in population and area is a small state, but the things she does are done in a big way. According to the 1910 census the state ranked fourteenth in the amount of its products turned out, this value totaling \$280,344,000. In the 1951 manufacturing establishments in the state there were in 1910, 114,000 wage earners, 46,000 of which were centered in Providence. From these figures one conclusion certainly is inevitable, and that is, that there is here a very evident necessity for control over the industrial welfare of the workers of the state. Nothing is more important to the public health than the conditions under which the average man earns his daily bread. It is in this field that conditions of good or evil have the most far-reaching influence upon the morbidity and mortality rates of the state and upon the health and welfare of the state's citizens.

From the point of view of responsibility another important factor is disclosed by the 1910

* Delivered at the Rhode Island Conference of Charities and Correction, Westerly, Rhode Island.

statistics,—a factor which may have been somewhat modified by the new State Labor Laws of 1912-13,—and that is the unusually large number of the especially susceptible women and children that is employed in the industries of Rhode Island. Of the total industrial population over 16 years of age, 36,000, or 32%, were women—the highest percentage in the United States. There were in that year 5,000 children under 16 years of age working in Rhode Island, 4% of the total industrial army,—the largest percentage in the United States with the exception of the child-labor cursed Southern states of North and South Carolina and Georgia. Unable to protect themselves, especially susceptible to many forms of industrial disease, this portion of the industrial workers makes a specially urgent appeal for protection to the conscience of the community.

It is not the purpose of this paper to discuss in particular Rhode Island conditions nor indeed to present in any detail the special features of occupational disease control. This is not an industrial hygiene conference and consequently for the most part the remarks shall be restricted to the more general features of the problem. It might be well, however, in so far as it is reasonable, to select our illustrations from the local field. Certain features of Rhode Island industry lend themselves most admirably to this treatment, as would be the case in any community.

As is universally known, the state (quoting again the 1910 census figures) was second to one other only in the manufacture of woolen and worsted goods and fifth in cotton textile manufacture. It is widely recognized that these industries offer especially difficult problems from the points of view of ventilation, dust control, etc., and in industrial hygiene are classified as dangerous trades, particularly because of the exposure to vegetable fibre and animal fibre dust. As might be expected, there results from this dust exposure an increased susceptibility of the pulmonary tissue to infection with a consequent increase in the morbidity and mortality rates from tuberculosis. It was found, for instance, in England and Wales in 1902, as reported by the Registrar General, that among males employed in cotton manufacture between the ages of 15 and 19, the death rate per hundred thousand from tuberculosis was 82 as compared with a rate of 54 for all occupied males of that same age period. The tuberculosis death rates for the woolen and worsted workers bore much the same relationship to the average, the rate per hundred thousand for woolen workers being 69 as compared with 54, the figures for all the workers in all industries. Undoubtedly the statistics for textile workers in this country, did we but have them, would illustrate fully as effectively the relation of this dusty trade to tuberculosis. It must be obvious that these conditions both at home and abroad cannot be remedied until certain specific preventive methods are universally applied. It is impossible to dis-

cuss in detail these corrective measures, but many of them are obvious, such as improved methods of ventilation, scientific dust removal, the wearing of respirators, the provision of eating and dressing rooms, general educational measures among employees by means of placards, leaflets, lectures, etc., a rigid and periodic medical examination, the discouraging of untimely female labor, the use of selected non-alcoholic labor, the development of intermittent labor with shorter hours and an attempt to retain regular employees, etc.

We are all aware that industrial disease is an important factor in the public health of any industrial community. Unfortunately, very few of our states have labor statistics sufficiently accurate to be used as a basis for determining the exact significance of this industrial disease factor. On the other hand, for the United States as a whole, based on extremely comprehensive German labor statistics, the American Association for Labor Legislation has estimated that by the 33,500,000 workers in the United States in 1910 there were lost because of sickness 284,000,000 days. It is estimated that the total financial loss in this year alone, including wages, loss to industry and medical cost, was \$772,857,000. This is not only a tremendous loss in efficiency, a great economic waste and an extremely poor conservation of human resources, but it is placing an unnatural limitation upon the social and economic welfare of the most vital part of our national structure—the great mass of workers. It is estimated conservatively that at least one-third of this disability is easily preventable.

It must be remembered that the average man in the United States is an industrial worker having a family depending for its health, progress and happiness to a large extent upon the man's working conditions. It is easy, no doubt, for social workers to understand the inevitable social and economic reaction between the work and the home. It must be remembered also that in certain instances industrial disease itself manages to reach indirectly through the worker to the home and its members. Everyone is familiar with the symptomatic picture of lead poisoning—its anemia, discolored gums, paralysis, blindness and insanity. This may be the picture of the male lead worker poisoned with the metal. On the other hand there are many cases on record where the disease has been acquired by the wife even when her only contact with lead industry was through the washing of her husband's lead-impregnated clothes, a poisoning preventable by the provision of factory dressing rooms and insistence on a change of outer garments upon leaving the factory. This is a particularly distressing picture because of the fact that lead poisoning is an affection of even greater seriousness in women than in men for they may add to the usual run of symptoms a sad succession of stillbirths and abortions. Sir Thomas Oliver has said that it

is practically impossible for a lead poisoned woman to give birth to a normal child.

It is impossible here to discuss in detail either the practical methods or the administrative principles of control. From a national and state point of view, however, it can be indicated in outline that the necessary controlling factors are somewhat as follows:

1. A thorough-going scientific labor law.
2. The coördination of authority.
3. Honest enforcement of the law including an adequate system of factory inspection.
4. Effective educational work.
5. An adequate system for the reporting of industrial disease.
6. A sickness and accident compensation system.

All Rhode Islanders are probably aware that one of the chief industries of their state is the dyeing of the textiles. As long ago as 1906 there were, according to the Rhode Island Commissioner of Industrial Statistics, 7,578 workers engaged in the dyeing trades. There is a particular poison associated with this industry as a result of the use of chrome dyes which, while not as serious as lead or phosphorous poisoning, is oftentimes incapacitating and consequently the cause of economic loss. The skin ulcers or chrome holes, as they are called, and the nasal septum perforations, are, on the other hand, easily prevented with the use of gloves and respirators. Another example of specific industrial danger to be found in the state is the manufacture of felt for felt hats where, in the impregnation of the hides with mercury, a dangerous poison is introduced into the felt and hat trades. The dust and fumes arising, if inhaled, absorbed or ingested, excite a frequent picture of mouth ulcers, insomnia, tremors, and sometimes fatal exhaustion, all of which can be prevented by dust removal, the use of gloves, mouth washes and tooth brushes and frequent dental and medical inspection.

Although there are many specific poisons occurring in industry, lead poisoning occurring itself in over 150 trades, nevertheless the great mass of workers are not subject to any special affection. From this point of view there would seem to be little foundation for the recent statement that under present social and economic conditions all industry is a disease. On the other hand, far outweighing the sequelae of specific toxemias are the more general evil results of unhygienic factory conditions and unwise labor stress such as the multiform neuroses and the cardiac and tubercular affections. We have touched briefly on the relationship of tuberculosis to the textile industry. A similar relationship is found wherever workers are employed under unhygienic and insanitary conditions for long periods.

As you probably know, Rhode Island leads the country in the manufacture of jewelry. In a statistical study conducted by Dr. Frederick L. Hoffman in 1908, it was found that in the

jewelry industry in the age period from 25 to 54, 59.5% of all workers dying, succumbed to tuberculosis, whereas the rate for the same age period for all industrial workers at that time was only 31.3%. Another Rhode Island industry is pearl and bone button making and it was found by Dr. Hoffman that for the workers in this industry for the age period 15 to 24, the percentage dying of tuberculosis was 50 as compared with a general rate for all the United States industrial workers of 27.8%.

Tuberculosis in industry is, of course, associated particularly with the dusty trades, and considering the various types of dusts that occur in industry such as the metallic, the mineral, the municipal, the vegetable and the animal, it is estimated that there are probably 800,000 workers engaged in dusty trades in the United States. In many factories and shops, moreover, we must add to the trade wastes the bad physiological and psychological effects of over-heating, the contamination from overcrowded workers and often excessive moisture.

We have not touched upon the degenerative affections and accidents consequent to the stress and strain of such an industry as that of iron and steel production. We have said nothing of the great field of industrial accidents and we must now ignore these industrial factors to consider for a minute what might be said to be, in roughest outline, the most urgent necessities of this state in the field of industrial welfare. There has not been time to make a careful study of local demands and consequently, to the knowledge of many present the following may be exceedingly incomplete.

In fifteen or more states there is a law relative to the reporting of occupational diseases. This law usually requires that the physician attending the case report to the proper authorities, either the Labor Commissioner or the Department of Health. A penalty of from \$10 to \$200 is affixed for failing to comply with the law. Now, two years ago such a bill was introduced in Rhode Island but after a hearing, was never reported. Of course Rhode Island ought to have such a law.

Most of you have heard of the disease known as the "bends" or caisson sickness, often associated with work under compressed air where proper precautions are not taken during the decompression process. The American Association for Labor Legislation has recently drafted a model bill on this subject and last year it was passed by the New Jersey legislature. This, or a similar enactment, is recommended by the Association for the state of Rhode Island. The Labor Legislation Association also intends to introduce in the Rhode Island legislature in January a sickness insurance bill which was drawn up by the Social Insurance Committee of this Association as a measure for use in the campaign for health conservation regarding sickness in industry, similar to the Safety First movement in accident preven-

tion. Thus can the state aid in the extension of the compensation principle to occupational diseases as well as to industrial accidents.

Of course, the citizens of Rhode Island are interested in workmen's compensation for employees of the Federal government. At the present time the Kern-McGillieuddy Bill, H. R. 15222, has been favorably reported by the Committee on Judiciary of the House of Representatives at Washington. This bill needs strong popular support and consequently letters and resolutions should be addressed to the Rhode Island representatives in Congress urging them to give their hearty support to this meritorious measure.

According to the December, 1913, Review of the American Association for Labor Legislation, "at least six branches of government are authorized or required to enforce labor legislation in this, the smallest state in the Union." This includes factory inspectors, the Bureau of Industrial Statistics, the Railroad Commission, the Inspector of Buildings, the school authorities and the police authorities and is sufficient evidence surely of the necessity for concentration and the coördination of control.

There is a great necessity here as elsewhere for constructive educational work in connection with the enforcement of sanitary and safety standards. This educational work should be carried on by the state, by the vocational training schools, by private philanthropic organizations, by labor unions and by employers.

There is needed here, as everywhere, the ability to make genuine value judgments in health matters. We spend money wisely for health when we attempt to control communicable diseases; we spend it foolishly when we attempt to make our health budget cover such non-health activities as plumbing inspection and nuisance abatement. From the point of view of health values industrial hygiene is of prime importance and we must realize that the health of the worker is essential if industrial evolution is not to be abortive.

There are many things of a more general, national or indeed international importance which must be taken into consideration especially by the creative, socially-minded individuals who are able to discern other than simply material values in industry and who are desirous of having palliation succeeded by prevention and cure in social reform. As a nation, we must realize in the first place the tremendous economic waste resulting from our national inability or disinclination to conserve the human resources in industry. Perhaps this will not be done until it is brought home to the industrial organizer that it actually pays to give at least as much attention to the human machine in industry as to the mechanical device. To quote a recent editorial in the *Journal of the American Medical Association*.

"Abbe (Zeiss Optical Works in Germany) kept a careful record for the years when

the plant was operating on a nine-hour day. When the working day was reduced to eight hours the record showed the men earned over 3% more than during the previous years, the output of the works was increased 3% and the power plant was able to shut down an hour earlier, thus affecting a very material saving in the fundamental expense. The record was for 233 men of 31 years and many different occupations on a piece-work basis were represented in the shop.

"Both employers and employees need to be convinced of the evident fact that the healthy man is the most efficient and the cheapest employee and that any reasonable expense to maintain him in health is a profitable investment."

It should be realized that our industrial system involves not only a waste of money and men but also of energy and enthusiasm. The men in Rhode Island who are making pearl buttons and who have nothing but pearl buttons to look forward to for the rest of their life are employed at a deadly hope-killing occupation and are quite naturally not going to put into that occupation any more interest and energy than is necessary. Is there a remedy for this? It is difficult to tell—certainly none has ever been tried on a large scale at least. One has been suggested, however, by an English writer and somewhat worked out by him in his discussion of the alternation of employments. This involves a periodic and progressive shifting from trade to trade at least in allied industries and requires of course intelligent governmental supervision, so necessary from every point of view, rather than the haphazard anarchistic industrial control or lack of control of today. This thinker believes, and certainly our own experience would seem to confirm it, that most men will work at a high pitch at a new thing, especially if they have in view a better thing to follow. In this way society would obtain both quantitatively and qualitatively a superior service from the individual, and as a result of the concentration would require less actual working time from the individual, thus allowing more time for the preliminary educational period, and because of increased earning capacity, a greater saving against the nonproductive old age.

Such a scheme would seem to be the only logical alternative to a further development of a more continuous specialization in industry, to a more fixed labor class and to the ultimate expression of the idea that man is first a worker and then a citizen as embodied in the pitiable program of "I. W. W. ism" in industry and syndicalism in politics.

It is inevitable that part of the labor of the world must always continue to be comparatively uncreative and unimaginative. However, the ultimate cessation of immigration, more immediate impending events in the industrial world,

point the way to the time, not far distant, when there will be no army of men always content to do "the dirty work" of the world. There is also a time coming when the state shall recognize the right of all individuals to work and grow socially and spiritually as well as materially—a thing scarcely possible for a man who is to be concerned with continuous drudgery or with one minute industrial process all his life. Is there a remedy for this condition? That also is hard to tell, but there is a plan, outlined by William James, that calls for an industrial state in which no class shall toil unceasingly but, through a conscript labor army, everyone, man and woman, will have the preliminary years for education and development, will spend his allotted time doing the foundation work of the world under the direction of the state on a basis of service to all, and not for the financial gain of the few. All the big necessities of life such as transportation, mining, food distribution and production, etc., must come under government supervision. For the individual to work his allotted time in this great industrial army will be to perform a great and recognized service to the state. Thus will drudgery be regulated and rendered innocuous. Here will be at last a legitimate field for militarism.

This may be exceedingly fantastic. It is at least, far in the future. It is an attempt to answer the many questions that are being asked of organized society with ever increasing intensity. Is industry to be reorganized by the intelligent, coöperative, sympathetic effort of a society with an awakened social consciousness, or is it to be seized and wrecked by the mad-dened and exploited? Is the spirit of gain to be replaced by the spirit of service or by the spirit of revenge? Is class distinction to grow and class war to come, or are the classes themselves to be socialized into extinction? Shall it be the constructive evolutionary path or the destructive revolutionary one? Shall poverty be enlightened and destitution made impossible? Pretty far from occupational disease? Yes and no. Far from the palliative treatment of this social defect but very near perhaps to the heart of the cure of the great social maladjustments of which preventable disease in industry is a manifestation.

MODIFICATION OF TECHNIC FOR HARE-LIP OPERATION.

BY W. E. LADD, M.D., BOSTON.

BELIEVING that perhaps there may be some surgeons besides myself who have had difficulties in performing hare-lip operations with uniformly gratifying results, I am offering a modification in the technic for their consideration.

The main principle of all hare-lip operations is the restoration of the normal line of the alveolar

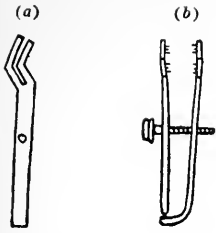

Fig. 1.

- (a) Shows front view of clamp with slit for knife.
(b) Side view showing teeth, etc.

Fig. 2.

Fig. 3.

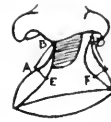

Fig. 4.

Fig. 5.

process as a preliminary procedure, followed by freshening of the edges of the fissure in the lip and sewing them together. In order to obtain a good looking lip with an inconspicuous scar it is absolutely essential to observe two rules: First the incision for freshening the edge of the fissure must be a clean cut made vertical to the plane of the lip; secondly, the incision on each side of the fissure must be of exactly the same length. Otherwise, accurate approximation is impossible and an unsightly irregular lip will result.

Some surgeons may be blessed with sufficiently accurate hand and eye to accomplish their result, "free hand," so to speak, but I believe there are many who will get better results by the use of instruments of precision.

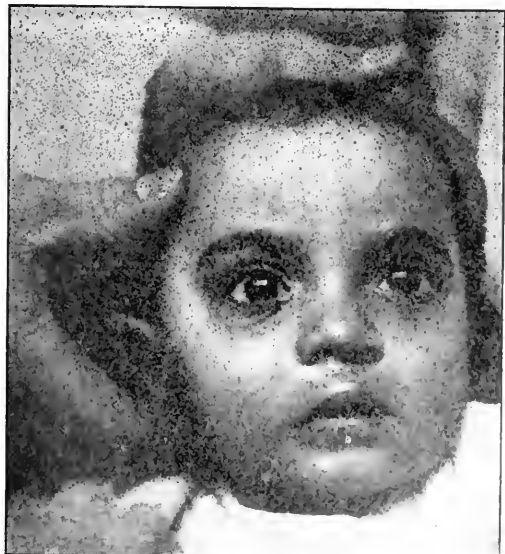

The ones which I have devised and found useful are two pairs of clamps (see Fig. 1), made on a suitable angle with fine teeth to prevent the skin or mucous membrane from slipping, and a slit for the introduction of a small knife to make the incision. The knife used is made double-

edged like a Catlin, only very small and thin (see Fig. 2). These instruments are used in conjunction with an ordinary small pair of sharp-pointed metal dividers. (See Fig. 3.)

The procedure of the operation is as follows: After the alveolar process has been restored in the usual manner, the desired height of the lip, minus the width of the vermillion border is determined with the dividers. This distance is then marked off on either side of the lip by pricking the lip with the sharp ends of the dividers at the points A and B and C and D (see Fig. 4) which are to form the lines of the incision. The lip and cheek are then freed from the alveolar process and superior maxilla on both sides until the fissure can be drawn together without tension. The clamps are then applied with the angles of the slits at the points A and C and the slits directed towards the points B and D. The knife is now introduced into the slit in the clamp and carried upward to the nose and downward through the border of the lip, making the incisions B A E and D C F (see Fig. 4). The

Hare lip before operation.

After operation.

clamps may now be removed and re-applied out towards the angle of the mouth to control hemorrhage.

The edges of the two incisions, which of necessity must be clean incisions of equal length and consequently fitting each other, can now be easily approximated, bringing the points B to D, A to C, and E to F (see Fig 5). This is done with one row of interrupted silk stitches, including all layers but the skin tied inside and another row of superficial approximation stitches of the same material, including the skin only, and tied outside.

This technic is applicable to all forms and varieties of single hare-lip, a fair example of which may be seen in the accompanying photographs before and after the operation.

Clinical Department.

PARTIAL TENOTOMIES BY THE TODD-HARMON METHOD.*

BY HOLBROOK LOWELL, M.D., BOSTON.

Assistant Surgeon, Massachusetts Charitable Eye and Ear Infirmary; Assistant Surgeon, Boston City Hospital.

NOTE: Since this paper was written the writer has become convinced that this operation was performed by Dr. F. C. Todd some six years previous to Dr. Harmon's article. Therefore the title has been changed, thus giving Dr. Todd credit for the precedence and Dr. Harmon credit for once more calling it to our minds in a most concise manner.

EVER since the writer began the practice of ophthalmology he has been particularly interested in heterophoric cases. He has tried blurring in esophoria, and prisms and exercises in exophoria. Tenotomies, tuckings, and advancements have produced fair and indifferent results. There has always been a feeling that it was rather a gamble as to just what result would be obtained in these cases. Some form of graduated tenotomy has always seemed the least haphazard and the more scientific procedure, but none of the numerous methods advocated have created enthusiasm enough for the writer to try them.

In the *Ophthalmoscope* of January, 1913, Dr. N. Bishop Harmon of London, England, published an article entitled "Lengthening a Rectus Tendon in Squint Operations." The writer was so much pleased with the simplicity and ease of control in the operation described that he has since, with gratifying results, performed the operation four times on patients with phorias, who had marked general and locally distressing symptoms. The liberty is taken of quoting below a portion of Dr. Harmon's article, to refresh the reader's memory.

*Read at the nineteenth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, October 20, 1914.

"The delicate methods of Stevens, Landolt, and Gromsdale require much patience, and then the result depends upon a frail suture. Verhoeff's partial plastic tenotomy is extraordinarily neat on paper, but is difficult to perform on the living subject, and I am not convinced that any real slacking of the tendon is secured. I evolved a method of three cuts which gave me all I wanted. It was so simple that it seemed that some one must have done it already, and in Casey A. Wood's new text-books of eye operations, I find nearly the same method figured, but if the author of the operation—Dr. Todd—will forgive me the criticism, it seems that he has just stopped short of doing what he sets out to do. The steps of the operation, and the effect, can be seen very well if it be practiced upon a piece of narrow adhesive strapping stretched between two fingers of an assistant. The tendon to be lengthened is exposed a short distance from the insertion. Supposing it to be an internal rectus, a small vertical buttonhole is cut parallel to the plica semilunaris and close to its edge. Tenon's capsule is cut and pushed back similarly, a squint-hook is passed beneath the tendon and slowly lifted, so as to draw the tendon into view, then two cuts are made in the same edge of the tendon, one on either side of the hook, as far as possible, so as to divide the tension at each cut up to the middle line of the tendon. Then the hook is pushed slightly to one side so the cut may be made from the opposite edge of the tendon, between the two cuts already made, and this cut is made from the edge right across the middle line of the tendon so as to sever two-thirds of its width. Immediately the third cut passes beyond the middle line, the tendon will be felt to give and it will yield distinctly as the cut is continued."

Discussions of this operation, and operations performed for the same purpose, elicited the opinion that the immediate result would be no more than ten degrees lessening of the phoria. In spite of the discouraging consensus of opinion, the operation was undertaken with some degree of confidence. In the following case the operation was done on the internal rectus of each eye.

CASE 1. Nov. 15, 1912, Mrs. H. W. F., myope, age 34, severe headaches for the past fifteen years. Examined repeatedly with and without a mydriatic. Complaints of pain through right eye, with no full relief from pain at any time. Appendix has been removed, turbinates operated upon, and an Alexander done. Has been in a sanitarium for nervousness several times. She is often awakened in the morning by severe pain in head. Fundi normal, pupillary reaction good, cornea clear, tension normal; small opacity in posterior surface of lenses. V.O.D. 20/30+, V.O.S. 20/70+. Esophoria seven degrees at twenty feet, tested with twelve degree prism base down, on the right eye. Esophoria between twelve and fifteen degrees at twelve inches. Homatropine ordered for examination.

Nov. 16, 1912. Ordered correcting glass with a three degree prism base out, in either eye.

Dec. 13, 1912. Above glass gave relief for four days, when same symptoms came back. Ordered:—
O. D.—.50 cyl. ax. 170 with 6 degree prism base out = 20/20.

O. S.—1. sph.—1.25 cyl. ax. 10 with 6 degree prism base out = 20/20.

Dec. 31, 1912. Last glasses do very well, though cannot read or sew, because she complains of seeing her nose. Esophoria seventeen degrees plus. Ordered +.75 added to her distance prescription with 6 degree prism base out, O.U.

Jan. 24, 1913. Old symptoms returned again. Partial tenotomy advised on left internal rectus. The operation was done according to the Todd-Harmon method, described above, the middle cut being carried a little farther than two-thirds the width of the muscle, as the greatest possible lengthening was desired. Immediately after the operation, prism base down before the right eye showed an esophoria of two degrees.

Jan. 29, 1913. There are no headaches at all. Esophoria three degrees at twenty feet. No movement with cover test. Ordered distance glasses prescription without prisms.

Feb. 12, 1913. Patient had severe headache again, complains of "pulling" of the right eye from inner manthus. Esophoria six degrees at twenty feet. Patient insisted that operation be done on right eye because of the "pull." Right eye was operated upon without incident, but the middle cut was not carried over two-thirds the width of the muscle, as only a moderate shortening was desired. The eyes were not tested immediately after this operation because of the patient's nervous condition.

Feb. 22, 1913. Conjunctival stitches were removed; orthophoria at twenty feet.

March 6, 1913. Cover test shows no movement. Feeling as though eye were "held in a vise" no longer present. Eyes white and quiet. Esophoria without glasses $1\frac{1}{2}$ degrees at twenty feet, with glasses $2\frac{1}{2}$ degrees.

Sept. 24, 1913. No movement with cover test, $2\frac{1}{2}$ degrees at twenty feet. Orthophoria, thirteen inches.

June 11, 1914. No movement with cover test, with and without glasses. Esophoria without glasses, at twenty feet, 2 to $2\frac{1}{2}$ degrees, with glasses 3 degrees. Patient says that she is free from previous headaches and other distressing symptoms.

CASE 2. July 24, 1912. Mrs. H. M. D., age 36, has had severe frontal headaches for past month; has been given glasses to rest eyes. V.O.D. 20/15—, V.O.S. 20/15—. Esophoria, twelve degree prism base down, twenty feet, fifteen degrees; at thirteen inches, nine degrees. Solution 1% homatropine ordered for examination. Ordered:—

O.U. +.37 sph. +.25 cyl. ax. 90 with 4 degree prism, base out.

Aug. 3, 1912. Complains of blurring with the new glasses but advised to continue using them.

Oct. 14, 1912. Esophoria has increased to twenty degrees at twenty feet. Ordered same prescription as above with 6 degree prism base out,

Nov. 7, 1912. Last glasses cause headache and general discomfort. It was decided to try a marked blurring glass with less prism. Ordered: +1.25 sph. +.25 cyl. ax. 90 with 4 degree prism base out O.U. Esophoria at twenty feet, twenty-six to twenty-eight degrees.

Nov. 19, 1912. Some trouble wearing glasses; advised to continue their use.

Jan. 28, 1913. Broke the last glasses. Esophoria twenty feet, twenty-seven to twenty-eight degrees. Marked movement with cover test. Operation advised.

Feb. 9, 1913. Operated on left eye, doing partial tenotomy. Middle cut was made as long as possible. There was so much pain resulting from stitching up the conjunctiva that the immediate result of the operation could not be tested.

Feb. 11, 1913. Patient had pain for about four hours after operation, but slept well. No headache.

Feb. 14, 1913. Some discomfort because of stitches. Esophoria twelve degrees, twenty feet. To wear old glasses.

Nov. 6, 1913. Esophoria fifteen degrees twenty feet.

June 11, 1914. Esophoria at twenty feet, with twelve degree prism base down, ten degrees; with Maddox rod fourteen degrees. Marked movement, cover test. Patient says she will have her other eye operated on next fall.

CASE 3. Apr. 7, 1913. Mr. W. F., age 62, marked diplopia. Cover test shows left eye turning up. Had considerable nausea, and much pain in back of his head, running down left side of his neck. V.O.D. 20/30, V.O.S. 20/20—. With +1. O.U. 20/15. Left hypertropia fifteen degrees. Operation advised.

Apr. 8, 1913. Partial tenotomy done according to the Todd-Harmon method on superior rectus, left eye. Orthophoria immediately after operation.

Apr. 21, 1913. Patient reports gastric symptoms have gone, and no longer diplopia, except when he looks very high up and to the right. Eight degrees left hyperphoria.

June 12, 1914. Four degrees left hyperphoria. Is not troubled by double vision, except when he looks up and to the right. Still some slight pain at times in left side of his neck. He has been so comfortable that it was necessary to write and ask him to report.

In summing up the foregoing results there are certain factors which should be taken into consideration. Patients with such marked phorias are of a highly strung, neurotic temperament, and it is a question whether this general condition is due to the phoria or vice versa. It is doubtful if it is ever possible to bring out all the latent phoria. However, the effort was made, in the first two cases, to bring out all the esophoria present.

In the first case the immediate post-operative result showed a correction of fully fifteen degrees. Eleven days after the first operation there were six degrees of esophoria and patient still had severe headaches. A few days after the second operation there were two and a half degrees of esophoria at twenty feet, that is, three and a half of the six remaining degrees had been corrected. In this second operation the middle cut was carried very slightly beyond the centre of the muscle. Fifteen months have elapsed since the last operation and three degrees of esophoria are present, the patient has freedom from the previous distressing symptoms, in spite of the fact that there has been much illness in the rest of her family.

In the second case the post-operative result showed a correction of fifteen degrees of esophoria, leaving twelve degrees uncorrected. The patient reports improvement in general condition and less nervousness, and wishes the other eye operated upon in the fall. There are still twelve to fourteen degrees of esophoria uncorrected.

In Case 3, the immediate result after operation was orthophoria. Fourteen months have elapsed since the operation, there are four degrees of hyperphoria present, showing an apparently permanent correction of eleven degrees. The patient has been comparatively comfortable.

Since this report was begun the writer has had occasion to operate on several strabismus cases. In two instances the external rectus was tucked, and the internal rectus was partially tenotomized according to Harmon's method. The procedure proved quite successful and gave a sense of security very foreign to that usually felt after a full tenotomy operation.

THE TREATMENT OF PNEUMONIA IN CHILDREN. REPORT OF 104 CONSECUTIVE CASES.

BY HAROLD W. DANA, M.D., BOSTON,

Assistant Physician at the Boston Dispensary; Second Assistant Visiting Physician at the Boston City Hospital.

THIS series of cases was treated by me during three years' service in Roxbury as district physician of the Boston Dispensary. There were 44 cases of lobar pneumonia and 60 cases of broncho pneumonia. Since I have not treated the two conditions as such differently from each other, the figures as to age periods include both types of the disease indiscriminately.

	NUMBER OF CASES.
Under one year.....	25
One year.....	21
Two years.....	15
Three years.....	12
Four to five years.....	14
Five to eight years.....	12
Eight to twelve years.....	5

Of the whole number treated, two cases died. One of these in addition to having pertussis as a complication, had taken almost no food in the week previous to beginning treatment. The other case, a feeble baby six weeks old, was not seen early in the disease. There was recovery in the other 102 cases. Many of these cases had pertussis or measles as complications to the pneumonia and in many cases treatment was not sought for until several days after the onset of the infection.

Home conditions were unfavorable in all of my cases in this series. The patients lived in a

poor neighborhood, in tenement houses; often the parents were very ignorant and many of them were opposed to modern theories of ventilation. The fresh air cure is difficult to give anyway where a family of from four to eight people live in two or three rooms. There was little to do with, and of course since the nurses of the District Nursing Association could at the utmost make but two daily visits, my treatment was based on this amount of nursing. While, naturally, constant nursing care would be more desirable, certainly no nursing could have been more efficient, painstaking and enthusiastic than that which these patients in Roxbury received. In most cases we obtained the loyal coöperation of the mother and I feel certain that the care given by the nurse and by the mothers of the children produced the favorable results obtained.

The routine was as follows, in order of their importance:—

1. Fresh air constantly. Often, in winter, a child can be kept better covered and warmer if it be bundled fairly tightly into a baby carriage or a clothes basket, when it is to be put near an open window, than if kept in a bed.

2. Food. This is extremely important. If one is willing to take the necessary time and trouble, small amounts of liquids, or semi-solid food can be given to any child, and if repeated often, considerable nourishment can be given. Often the fact that a sick child does not wish food is considered by the mother as a sufficient reason for not giving the child any food.

3. Saline enemata. Long, slow, hot normal saline irrigations of the bowels once or twice a day are useful as a means of stimulation, to give water to the body, to reduce toxemia, and also for cleansing purposes. If necessary, calomel in divided doses was used for distention or constipation.

4. Cold applications to the chest. This was accomplished by wringing cloths out of cold water, applying them to the skin, covered over with newspaper to protect the clothes. These applications should be renewed when they become warm.

5. Bathing. These children received a tepid sponge bath, preferably followed by an alcohol rub, twice daily if the temperature reached 102.0° F.

6. Brandy. When the temperature is high or long continued I am personally in favor of large doses of brandy, perhaps 20 to 50 drops every two hours for a child one to three years old. The brandy is better not given with food as it may make the child vomit, or may make the food objectionable to the patient.

7. In one case in which I suspected a streptococcus septicemia, as a sequel to the pneumonia, antistreptococcus serum was given twice, apparently with brilliant results.

8. Drugs. As a routine all of these patients were given ammonium chloride and syrup of ipecac, using the fluid extract of glycyrrhiza as a

vehicle. For a child under a year I use a quarter to a half grain of ammonium chloride and a quarter to a half drop of the ipecac each two hours. For all children over a year I give a drop of ipecac for each year of the child's age each two hours, and a grain of ammonium chloride each two hours for a child from one year to twelve years old.

If the child is very sick, it is given tincture of belladonna, a quarter to a half drop up to eighteen months of age, and one to one and a half drops for older children each two hours.

A method I have found convenient for prescribing these drugs, is to add together the number of drops or grains of each ingredient desired in one dose, and then to order as many drachms of each to be put into the mixture as there were drops in each dose. For instance, for an eighteen months' old baby if I wish to give a grain of ammonium chloride, a drop of belladonna, a drop and a half of ipecac, using five or six drops of the vehicle, I write for the following mixture:

R Ammonii chloridi	3i	(=gr. 1)
Syrupi ipecacuanhae	3iss	(=Gtt iss)
Tincturae belladonnae	3i	(=Gtt i)
Extracti glyceirrhizae fluidi	3vss	(=Gtt vss)
(Total =8 drops)		

M Sig. Give eight drops in a spoonful of boiled water every two hours.

As sheet anchors in case of need I use, first, tincture of digitalis, based on a minim and a half dose for each year of age each four hours when the heart action is weak and rapid; finally, as a last standby, I make a solution of strychnine sulphate and give large doses, one four-hundredth to one one-hundredth of a grain every four hours, stopping this drug after a day or so, or as soon as I can, to hold it in reserve for further need.

Medical Progress.

SEVENTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY.*

By ROBERT B. OSGOOD, M.D., ROBERT SOUTTER, M.D.,
HERMANN BUCHOLZ, M.D., HARRY C. LOW, M.D.,
MURRAY S. DANFORTH, M.D.,
BOSTON.

TUBERCULOSIS.

TUBERCULOUS rheumatism still continues to be discussed and the French seem to have won a German convert. Nohl¹ believes that a chronic

* This report is based on a review of 260 articles, etc., selected from about 500 titles having to do with Orthopaedic Surgery appearing in medical literature between December, 1913, and March, 1914. References are given to only such articles as have been chosen for report and comment.

affection of the joints with a dragging course, a tendency to ankylosis, and a lack of response to the salicylates, should lead one to suspect tuberculosis as the cause. If, in addition, the general health is more affected than the condition of the joints seems to warrant, Nohl believes that we are safer in treating the case as one of tuberculosis.

Raw² reports several cases in which there was a polyarticular "tuberculous arthritis" in patients having other severe tuberculous affections, either glandular or general. On the other hand, there was no evidence of arthritis in 6000 cases of pulmonary disease.

[Ed. Note.—The evidence which Raw presents does not go far to prove the frequent occurrence of the rather mild "rhumatisme tuberculeux" which Poncet has described.]

Menard³ states his belief that the only efficient method of treating Pott's disease, both as regards cure and the prevention of deformity, is by recumbency. Menard's experience is perhaps as large as that of any orthopaedic surgeon, and he is not unfamiliar with the work of other men.

Packard,⁴ after many years of work, has reached the same conclusion.

[Ed. Note.—We believe that greater effort should be made, even among the poorer classes, to carry this out in all severe cases. We still consider too early weight bearing unwise, even if ankylosing operations have been successfully performed, though they may well shorten the period of recumbency.]

We continue to see favorable reports of the treatment of osseous and joint tuberculosis by means of the Roentgen ray. Biteroff⁵ has observed some thirty cases treated in Wilms' clinic in Heidelberg between October, 1911, and April, 1913. In twelve cases a later examination was made and in nine others reliable reports were received. Among the twenty-one cases there were four which he excluded because of tuberculous disease elsewhere, but among the seventeen remaining, twelve showed definite cure, two a probable cure, and three considerable improvement. The sinuses closed in all cases within a few months. He recommends the removal surgically of as much of the diseased tissue as possible and insists upon general treatment being carried on at the same time.

Seaduto⁶ has observed five cases treated by this method, i.e. by post-operative Roentgen ray exposures every two weeks for many months. He considers the combination a great progress in the treatment of tuberculosis of the joints.

[Ed. Note.—The benefit of Roentgen ray therapy in tuberculosis of the joints would be more conclusively proven by these reports if general and surgical treatment had not gone hand in hand with the Roentgen ray therapy. We are inclined to believe, however, from personal experience that in certain cases, especially those with sinuses and mild secondary infection, this method should be tried with some measure of hopefulness. We must never forget, however,

the danger from x-ray burns or its effects upon the deeper glandular structures.]

Leuba,⁷ evidently tremendously impressed with the cures in Rollier's clinic at Leysin of cases of tuberculous disease of the foot, many of them very advanced, declares that it is criminal to operate upon such cases. Many of these cases had been advised to have amputation performed and the photographs would seem to justify this advice according to the experience of the past.

[Ed. Note.—While the paper adds other evidence of the great value of heliotherapy as carried out at Leysin, there will remain many cases to be treated, which can neither go to Leysin nor remain inactive for the long period necessary to carry out the treatment by heliotherapy in any place. The results of tuberculosis of the foot and ankle as studied by Rogers⁸ would seem to indicate that surgery under certain conditions is still the best method of treatment.]

Mau⁹ has found in the blood of a large number of tuberculous patients and also of persons in health, acid-fast bacilli. He has not conclusively proved that these are tubercle bacilli, but believes them to be. He makes a plea for the consideration of tuberculosis in all its manifestations as a general disease and urges the continuation of general treatment for many years after the local lesion is apparently healed.

Küchenhoff¹⁰ points out the fact that spinal anomalies may well prove a predisposing cause of pulmonary tuberculosis, especially to apical lesions, because in the "round shouldered" position with the curve of the upper spine forward, the apical space is narrowed.

[Ed. Note.—This observation is in keeping with statistics which show the common development of tuberculosis in persons whose chest expansion is slight and also in keeping with the fact that faulty posture and round shoulders are seen to be almost universal among those who make up the personnel of a tuberculosis clinic.]

Interesting inoculation tests have been made by Sforza and Cosco.¹¹ They have attempted to determine the extent to which muscle and bone marrow harbor the tubercle bacilli. They removed portions of muscle and bone marrow from tuberculous cadavers and injected them into guinea-pigs. In forty experiments they found practically no signs of infection when the pigs were inoculated with muscle tissue, but nearly all which had been inoculated with bone marrow died.

ARTHRITIS.

While acute articular rheumatism is considered a medical rather than an orthopaedic disease, the increasing tendency to seek at least the consultation of the orthopaedic surgeons in all chronic and some acute joint diseases makes any investigation as to the etiology of acute poly-arthritis of obvious importance in any review on progress such as this. As is well known, Poynton and Paine many years ago believed they had

isolated a specific streptococcus from joints of acute articular rheumatism. Phillip, Cole, Beattie, and others failed to cultivate any streptococcus, and Loeb was successful in only a few cases.

Rosenow's¹² experiments with his careful technique and detailed reports are of extraordinary interest. He seems to have isolated three types of organism from the joints of two cases, each of which types by special cultural methods may be converted into either one of the other two. Two of these, a streptococcus and a micrococcus, produced arthritis and pericarditis, but not myositis in rabbits and monkeys. They are all of low virulence and their affinity for joints and endocardium diminishes in cultivation. Grown with other bacteria and under low oxygen pressure, such as exists in the tonsils, sinuses, etc., they may acquire new features.

[Ed. Note.—Rosenow appears to be a veritable prestidigitateur and his successful transmutations are most astonishing. The confirmation of these observations will be of great importance. and in the meantime, as he suggests, we may well retain the term "streptococcus rheumaticus" until we can more carefully differentiate these varieties. The possible bearing of these experiments on vexed questions of the bacteriology of the different chronic non tubercular arthritides is evident.]

Barker¹³, after an exhaustive study of the literature, finds that "the differentiation of the diseases included under the term chronic arthritis" is not so obscure a problem as he had expected. He recognizes along with others the almost impossibility, in the light of present meagre knowledge, of making a satisfactory etiological classification. There are too many missing links in the development of these diseases. Moreover the same late clinical picture may be present as the result of two very different original causes. An anatomical classification offers more hope and is more satisfactory than such terms as "static arthropathy" (Preiser) or "chronic irritative arthritis" (Hoffa and Wollenberg), but again our accurate anatomical and pathological knowledge is not at present accurate enough to make possible a satisfactory and inclusive classification on this basis. Barker recognizes the vitality and accuracy of certain descriptive terms and believes that much of the confusion which still exists is due to the attempt to make clinical and anatomical and etiological classifications coincide. As a working basis he suggests four divisions: I. Gout. II. Neuro Arthropathies. III. Primary Hypertrophic. IV. Secondary Chronic, including under this last heading Infectious Arthritis, as Luetic, Tuberculous, Gonorrhoeic, Rheumatic (if it exists).

[Ed. Note.—It may not be amiss for the Editors to synonymize some of the various English and American attempts at classification under these headings.

I. *Gout*. This seems to retain its specificity in most classifications.

II. *Neuro Arthropathies*. Evidently here are included the tabetic joints, those occurring in syringomyelia, and possibly some of the types of atrophic arthritis (so-called by Goldthwait), which Osler and Painter and others have supposed to be possibly connected with a lesion of the central nervous system.

III. *Primary Hypertrophic*. This would obviously include the Hypertrophic type of Goldthwait and the Degenerative or Non-ankylosing type of Nicholas and Richardson, the Chronic rheumatoid type of Bannatyne, and the Osteoarthritic type of Llewellyn Jones. When speaking of Heberden's nodes, which belong under this heading, many writers use the term "Arthritis deformans." Strictly speaking this should be used as a general term for any deforming arthritis rather than as indicating any one type.

IV. *Secondary Chronic*. In this group should be included all those chronic joint conditions following special known etiologic agents, the great mass of which are either frankly infectious or at least toxic from some focus away from the joints. Here we should place probably some of the Atrophic and all of the Infectious types of Goldthwait, and the Acute and Subacute rheumatoid types of the English writers, and the Proliferative or Ankylosing types of Nichols and Richardson, although these authors believe that the causative agent is not an infection.

We have not mentioned in this attempt to synonymize the careful pathologic classification of Nathan, for while it is most helpful and valuable, it is less likely to be applicable clinically by the average practitioner. What we need at present more than anything else is the general recognition of such rudimentary facts as the very existence of specific types of chronic non-tuberculous joint diseases, now far too widely classed as chronic rheumatism and treated by irrational medication and meagre success. When the profession at large comes to accept these facts, evident to all historical and clinical and pathological investigators, and learns to recognize the various types, calling them by what names they will, then we may expect less discouragement of therapy and a more rapid advance of knowledge which will some day lead to more accurate and generally acceptable classifications.]

The importance and possibility of this differential diagnosis of these types has been emphasized by Wollenberg¹⁴ in a recent article, in which by pathological specimens and radiographs he shows the findings to be quite characteristic of gout (Type I, Barker), arthritis deformans (Type III, Barker), progressive polyarthritis and gonorrheal arthritis (Type IV, Barker).

In an article entitled, "General Pathological Considerations in Joint Affections," Delrez¹⁵ has made some interesting observations regarding the joint fluid. If the cytological examination of this shows the polynuclear count low it argues in favor of a tubercular infection. Only the

presence of bacteria themselves, and not the cell count, would determine whether the fluid were sterile or infected, since this cell count varies in both types at different times, now showing a preponderance of the polynuclear forms and now of lymphocytes. If the fluid withdrawn does not coagulate in thirty minutes it suggests complete recovery. When spontaneous coagulation occurs outside the joint this usually takes place in from ten to thirty minutes. Delrez has found, as have other observers, that the synovial fluid may be sterile but bacteria be found in the membrane. Analogous conditions are found in the pleural, pericardial, and peritoneal cavities. He states that Volkmann and König have shown that tuberculous arthritis is frequently caused by a neighboring bony focus and that J. Koch was able by injecting a streptococcus in the vein of a dog to produce an arthritis. The fluid withdrawn was sterile, but the streptococcus was found in the marrow, the epiphysis, and the periosteum. Delrez believes, however, that there are also articular infections primary in the synovial membrane, and quotes the experiments of Lannelongue and Archard on rabbits, proving absolutely in his opinion this independent origin of certain infections in the joint synovia with the bone uninvolved.

Pemberton¹⁶, using the term Rheumatoid arthritis in a somewhat indefinite and inclusive sense, has been studying its metabolism and attempting to discover methods of diet which will be preventive and successful in the treatment of chronic polyarthritis. We should say that most of his cases would come under the fourth type of Barker's classification above, that is, the Secondary Chronic Type, and would not include the third, or Primary Hypertrophic class. Pemberton points out that even the removal of the original cause may not be sufficient to put the disturbed metabolism in correct balance. He believes that the old ideas of faulty elimination of the bowels and kidneys and of intestinal putrefaction must not be too closely followed. His treatment is based on the regulation of the diet so that it shall first come within the limits of the disturbed faulty metabolism. That is, he begins frequently with a diet of low calorie value and with quite as much attention to the avoidance of too great quantities of carbohydrate food as of proteids. The diet is then increased very gradually. He has found this successful in markedly improving the condition in many reported cases.

[Ed. Note.—His articles are well worth careful study, not only because of the value of his research work, but because the emphasis is rightly laid upon careful individual attention to each case in the matter of diet. Little may be expected from any other type or dietetic treatment.]

It may possibly be found as a result of the most suggestive studies of Traves¹⁷ and Dreike¹⁸, the later work of Bean¹⁹ on the basis of the germ layers, and the still more recent articles of

Bryant²⁰ on personal records of over 200 autopsies, upon which we expect to comment more fully in a later Report of Progress, that we shall be able to lay down certain broad principles of diet, based on an ability to recognize certain broad general types of individuals and based also on the possible discovery that the different types are susceptible to distinct types of metabolic and joint disturbance. Thus many observers have recognized already the carnivorous and herbivorous types and the difficult intermediate class of human beings, the body form, the lengths of the different intestinal segments, etc., all conforming to a most constant degree. Already we are beginning to find clinically that one type does well on a largely meat diet, and badly on a largely vegetable, while another improves on vegetables and grows worse on meat. We would call the attention of those interested in this most suggestive, and we believe most helpful work, to Bryant's²¹ Remarks and Bibliography on Stasis and Human Efficiency in the May, 1914, International Abstract of Surgery.]

Menzer²² believes that all treatment of non-tuberculous joint diseases should proceed on the assumption that somewhere in the body is a focus of chronic infection. He considers that the commonest location of these central infections is in the upper air passages, the tonsils, the nasal sinuses, the bronchial lymph nodes, or the ear.

Ibrahim²³ is convinced that Still's disease is identical with chronic infectious polyarthritides of childhood and that the prognosis in all cases is by no means bad.

[Ed. Note.—We report these articles not as representing new conceptions but as adding the weight of further clinical observations to the infectious or toxic theory of much chronic non tuberculous joint disease. The acceptance of this theory will lead to the realization that as Menzer says, salicylic medication is not the proper treatment. It may relieve pain, but it does not combat the central primary cause, and interferes with the natural production of antibodies and the development of natural immunity.]

Tommasi²⁴ interested in a statement of Prof. Pellizzari that gonorrheal arthritis occurred only in tuberculous subjects, studied all the cases of gonorrheal arthritis admitted to the clinic of the R. Istituto di Studi Superiori of Florence from November, 1911, to the date of his paper, comprising twelve cases. A positive diagnosis of tuberculosis was made when the von Pirquet reaction was positive. A positive diagnosis of gonorrheal arthritis was made when there was in addition to a characteristic arthritis a urethritis with a discharge containing gonococci. In every one of his twelve cases there was a positive von Pirquet reaction and nearly all were of a "build" suggesting susceptibility to tuberculosis. Some of the cases had evidently had previous tubercular infections. Tommasi believes that in a person infected with tuberculosis the tissues may be predisposed to gonorrheal in-

fection, the protective reaction being weak to this special infection. He believes that the very fact that a person has a gonorrheal arthritis should lead one to suspect a latent tuberculosis and that treatment should be planned with this in mind.

Solis-Cohen²⁵ has called attention to a very obscure but, we believe, sometimes recognizable class of joint symptoms which he designates as angioneural arthroses (periarthroses, pararthroses). The etiology is obscure, and attacks come on and recovery occurs often unexpectedly and inexplicably. Practically nothing is known of the pathology, and the diagnosis may perhaps be said to be made largely by exclusion. The type of individual is usually neurotic and the exacerbations seem now to have one cause or set of causes and now another. He does not attempt to discuss the possible relation of any of the glands of internal secretion, but believes that supervision and regulation of the manner of living is of most importance.

Over treatment is, in the opinion of the editors, the greatest danger, considering our great lack of knowledge concerning both cause and effect.

PARALYSIS.

Cerebral-Spastic. Stoffel's²⁶ article on the treatment of spastic paralysis is an important one and we are beginning to receive reports, for the most part favorable, concerning the results of the operative treatment which he advises in certain cases. He believes, however, that early cases can be much benefited by non-operative treatment. He emphasizes the fact that there exists no complete paralysis of muscles in spastic paraplegia. The peripheral neuron being intact, the muscles are capable of contraction under electrical stimulation. He considers that there are two stages to the disease, first a more or less complete paresis and a diminution in muscle tone; second, a state of hypertonicity in those muscles whose origins or insertions are brought nearer together by the positions maintained in bed, and a hypotonicity in the over-stretched groups. He believes that if contractures are not allowed to occur, the primary stage of paresis is curable and that the muscles can be re-educated into good function. In the cases such as are commonly seen in which contractures have already occurred, Stoffel believes that decreasing the energy of the spastic muscles and increasing that of the antagonist muscles is the principle of treatment to be followed. He considers that this can most perfectly be accomplished by an operation which he describes. With a knowledge of the internal anatomy of the nerve bundles within the sheath, he resects or divides some of the motor fibres going to the spastic muscles. By massage, exercises, and electricity he then strives to strengthen the weaker antagonists. He resorts in addition to tendon lengthening only when contracture is still present under the anaesthetic.

Hohmann²⁷ reports good results (number of cases not given) from this operation, but emphasizes the importance of long continued after treatment, and has noted the appearance of neuralgic pains in two of his cases one and two weeks respectively after the operation. He believes that the operation is indicated in cases of Little's disease, infantile cerebral hemiplegia, and spastic contractures in the hemiplegias of adults, but not indicated in those cases having choroeic movements, hydrocephalus, etc.

Bülow-Hansen²⁸ in Christiania reports his favorable experience with the operation in 22 cases, nine of Little's disease, eleven of spastic hemiplegia, one of spastic hemiplegia in an adult, and one a spastic torticollis.

Bundschuh²⁹ from the surgical clinic in Freiburg describes two cases of spastic equino varus and one of marked adductor contracture who were much benefited by the operation.

Kölliker³⁰ in Leipzig, on the other hand, believes from his experience that the operation is not as suitable as tenotomies in cases of Little's disease, but is useful in pronation and flexion spasms of the hand in cerebral hemiplegia.

A type of spastic paralysis occurring in certain cases of inherited syphilis, described by Marfan³¹ should be mentioned, since it may well be confused with some of the other spastic paralyses. With treatment it is capable of cure, alleviation, or at least arrest, but without treatment is definitely progressive. Marfan has observed six cases, the paraplegia beginning between the ages of five and twelve. The gait at first is only a slight limp of the spastic type and may be more pronounced on one side. It is difficult for the child to flex the joints in walking, though the spastic rigidity largely disappears at first in sitting or reclining. The tendon reflexes are much exaggerated and Babinski's sign is present. In Marfan's cases the Wassermann was positive in several and in three there were signs of an interstitial keratitis. Salvarsan seemed effective in arresting the process in his first case (observed for over ten years) though mercury and iodide had failed. If treatment is begun early he believes the progress may be arrested and possibly a complete cure accomplished.

Poliomyelitis. Kling and Petterson³² add confirmatory evidence to the experiments carried out at the Rockefeller Institute under the direction of Dr. Simon Flexner, with regard to finding of the virus of poliomyelitis in the washings from the nose and throat of healthy persons in the environment of a case of poliomyelitis. It would seem that whether or not the disease is transmissible by insect or animal carriers, the human naso-pharyngeal secretions should be most thoroughly destroyed in all cases of the disease, and perhaps as well the secretions of those in close contact with the sick.

Soutter³³ has devised an operation for the correction of the obstinate flexion contractures of the hip frequently observed in neglected cases of poliomyelitis. Its merits are its thorough-

ness, its simplicity, and its freedom from hemorrhage. A 6-8 cm. longitudinal incision downward from about 5 cm. posterior to the anterior superior spine is carried to the deep fascia, which is then incised in a transverse direction. With an osteotome or a sharp periosteal elevator the insertions of the tendons to the anterior superior spine and extending downwards along the pubic bone are scraped off and pushed downward with fingers and gauze. The bleeding is slight and the correction of the deformity easy.

[Ed. Note.—The editors have had most satisfactory results from this operation.]

Under the title of "A New Treatment of Poliomyelitis," Moulton³⁴ maintains that many cases of poliomyelitis may be prevented from permanent paralysis by energetic manipulative treatment of the spine. Quoting Osler he says that the paralysis is due not so much to the damage to ganglion cells themselves as to the effect of the inflammatory changes in the surrounding tissues. He believes that regeneration of the axis cylinder will take place if the nourishment can be restored. The inflammatory process has caused adhesions of fibrinous tissue which contract and constrict. By stretchings and swingings with the body suspended by the head or a waist belt he strives to break up these adhesions without injuring the nerve cells, bringing about at the same time an increased blood supply which aids absorption and stimulates vaso motor function.

[Ed. Note.—Moulton's reports of cases are vague, and while the possibilities of his treatment need not be denied, it is evidently unscientific and certainly in the early cases, we believe, dangerous. In our experience massage begun before the peripheral neuritis had subsided has aggravated the symptoms. With certain safeguards and with judgment its trial in cases beyond the acute stage would not seem likely to do harm, but would seem to differ little from the methods now employed by those well trained in physical therapy.]

(Concluded next week.)

Reports of Societies.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

WEDNESDAY, NOVEMBER 11, 1914, AT 8.30 P. M.

The President, DR. WILLIAM DUFFIELD ROBINSON, in the chair.

DR. JOHN J. GILBRIDE reported a case of acute appendicitis with abscess formation in which the infecting organism was the colon bacillus, and in which the patient had a severe glycosuria. Recovery followed operation and drainage.

SYMPOSIUM: THE EYE, THE EAR, THE FAMILY DOCTOR.

DR. GEORGE E. DESCHWEINITZ read a paper entitled "Concerning the Commoner Diseases and Injuries of the Eye and Their Treatment."

DR. SAMUEL D. RISLEY: Under the light of modern research we have discovered that things apparently simple are complex. In no form of disease is this probably so much observed as in conjunctivitis. By the educated eye and with laboratory methods many essential differences are discovered not recognized by casual observation. We all must have been impressed with Dr. deSchweinitz's statement that to be an ophthalmic surgeon one must first of all be an educated doctor. With increased experience I am more impressed with the truth of what has been said tonight, that if tubercular infection of the eye does not stand first as an etiological factor in infections of the uveal tract and of the cornea it is very close to first in etiological importance. Again and again cases of headache have upon close study been traced to this infection.

DR. WILLIAM S. NEWCOMET: Reports come to us from outside the city of cataracts being cured by radium, but I cannot support any such form of treatment. We occasionally get good results with radium in the treatment of small epithelioma around the lids. In cases of true rodent ulcer, however, I believe we gain nothing, unless we cut wide of the mark and bring the tissues together by a plastic operation. In reported cases of cure there is failure to discriminate between the two conditions.

SOME CONSIDERATIONS OF THE NEWSPAPER ELEMENT IN PUBLIC MEDICAL INSTRUCTION.

DR. HIRAM WOODS, Baltimore: From the attempt of the medical profession in Baltimore to make use of the public press certain lessons have been gathered. Three phases of our relations with the daily press are: (1) Advertisement of patent medicines, various medical appliances, electrical treatment, opticians' cure of remote symptoms by glasses, etc.; (2) Descriptions of remarkable, or supposedly remarkable operations, details of illness of prominent persons, etc.; (3) Legitimate educational purposes. The first of these three, advertisement, has an influence upon the value of an educational article. Certain classes of people receive more lasting impressions from the claims of some medicine published on the first or last page than from a carefully prepared article stowed away in small type on the editorial sheet. Upon the second count we have found that men whose cases did not, and others whose cases did get into the papers, disapproved of the publication of unauthorized accounts of an illness or surgical operation. A committee was appointed from our profession to confer with the newspaper representatives. The report of our committee, however, failed of acceptance with two out of three newspapers mainly because editors did not wish to curtail their plans for running down a "story" in their own way. In our relation with the press, no one will question the value of the newspaper as a means of reaching the public, there can be no doubt of public interest in medical matters; and, I think we may also say that if we have advanced in preventive medicine, it is our duty to instruct the public in means of prevention. To make such instruction helpful, however, one must put himself in the place of the ignorant and the more or less sensation-loving portion of the public, those

most in need of our instruction. For this work the help of the experienced reporter should be welcomed.

One point especially insisted upon by our Baltimore newspaper friends is that medical articles should be signed by a man known to understand his subject. Success in newspaper instruction must depend upon professional and journalistic coöperation. Possibly the solution lies in the medical society's assuming responsibility for the article, while giving the name of the author. Newspaper public instruction has more to it than furnishing anonymous articles and the background difficulties are the hardest to solve.

DR. A. B. HIRSH: That there should be united action on the part of the medical profession and of representative men of the press certainly appeals to those who have studied the efforts of our own County Medical Society's committees in what has been to us during the past year a relatively new field. Dr. Woods has our assurance that his suggestions have indeed fallen upon fertile ground.

THE RELATION OF THE TONSIL, ADENOID AND HEARING TO DEVELOPMENT IN CHILDREN.

DR. D. BRADEN KYLE: Tonsillar and adenoid tissues are physiological structures and their relation, as well as that of hearing, to the mental and physical development in children is of extreme importance. It is therefore apparent that the mechanical interferences with phonation, such as imbedded or enlarged tonsil, or the obstructive adenoid, should be corrected early in life before habits are fixed. Extreme care should be taken in correcting these defects that the muscular structure of the soft palate and pharyngeal pillars are in no way injured and thereby prevent the formation of scar tissue, which in turn would involve the mechanism of phonation later in life. It is extremely important for the parent, the physician and the teacher to take into consideration these mechanical defects, and watch the process of the child through the formative period of development. I do not wish to be understood as believing that all tonsils cause adverse conditions or that all tonsils should be removed, but I do wish to emphasize my conviction that adenoids and tonsils are in many instances the great enemies of perfect development of hearing and of speech. There are few children who suffer from impaired hearing who do not have this condition. There is no more fallacious and dangerous statement in the English language when applied to the ear, than that advice of letting the child alone to outgrow the cause, for we positively know that sooner or later it will be a menace, not only to his hearing but to his speech and general health. While the child's mentality may be normal more effort is required to attain development in the presence of obstructive adenoid structure than in its absence. In early childhood any obstruction to nasal breathing will affect the facial development and contour. This will affect the acoustics of the mouth and interfere with phonation and enunciation and alter the voice. The tonsil that is submerged is the one that nearly always is to blame for the infective processes in its region and in the neck and which proceed from the neck to the general system.

By careful attention to these conditions in childhood with removal of the causes the number of handicapped children will be materially lessened.

DISCUSSION.

DR. B. ALEXANDER RANDALL: I would express my almost complete agreement with all that Dr. Kyle

has said. I will go a step further and state my conviction that obstructed nasal breathing is more often a cause of adenoid hypertrophy than a consequence. We must have a free nose if we are to have these conditions remain anywhere near the normal. Unilateral deafness is a very serious handicap to those who may have perfect hearing in the other ear. If all sounds are taken in from one ear there is not only a delay in comprehension, but an amount of actual confusion very little appreciated. Upon the anatomical side I feel strongly about the essential nature of a free nose. There are many instances in which the high vaulted palate with the narrow nasal chambers are in part hereditary. Children should be taught early to keep the nose free. By hot gargling much can be accomplished by a method so ridiculously simple that many will not use it. By keeping the parts in good working order in early life many of these disadvantages can be forestalled.

DR. FRANCIS R. PACKARD: In a discussion of the pathologic conditions of tonsils and adenoid vegetations in the nasopharynx as they bear on the development of the child, there should be a distinction drawn between the two conditions. In respect to the influence of adenoid vegetations, I think their presence is invariably harmful, especially (1) by their interference with respiration; (2) by the ear conditions, either suppurative or nonsuppurative to which they give rise; (3) as sources of infection by the presence in the adenoid of tubercle bacilli or other pathologic microorganisms. Meyer's classic report which appeared in English in the Transactions of the Medico-Chirurgical Society of London for 1868, dwelt especially on the ear troubles arising from them, nearly two-thirds of the 102 cases he had observed having aural disease as a result of the presence of vegetations. The tonsils although sometimes an etiological factor in ear troubles and quite often a source of respiratory disorders, are now chiefly regarded as productive of harm by acting as portals of infection or autotoxemia, especially in what are grouped as rheumatic affections of the muscles, joints or heart, and of those general, slow toxic infections of which, heretofore, the source has been regarded as obscure.

Book Reviews.

Chemistry and Toxicology for Nurses. By PHILIP ASHER, Ph.G., M.D., Dean and Professor of Chemistry at the New Orleans College of Pharmacy. Philadelphia and London: W. B. Saunders Company. 1914.

This new volume in the publishers' series of text-books for nurses is intended as an elementary manual for probationers, and a reference work for graduates. After a preliminary consideration of nomenclature, the chemical substances used in medicine are described, with their medicinal properties, doses, and uses. The book is in three parts, dealing respectively with inorganic, organic, and physiologic chemistry. The

toxicology of poisonous substances is considered in conjunction with each. There are three text-figures representative of apparatus. The book is concise, well arranged, and should prove of use and value to those for whom it is written.

A Medical Dictionary for Nurses. By AMY E. POPE. New York and London: G. P. Putnam's Sons. 1914.

This convenient new dictionary aims to provide the derivation, pronunciation, and detailed definition of medical words and terms of special importance to nurses. The dictionary, which occupies thirteen-fourteenths of the volume, is followed by supplementary tables of weights, measures, chemical symbols, abbreviations, elements, poisons, prefixes, suffixes, thermometric scales, and the average composition of common American food products. The book should prove of value to nurses and others in search of this type of information.

The Life and Letters of Nathan Smith, M.B., M.D. By EMILY A. SMITH. New Haven: Yale University Press. 1914.

This volume, published at the time of the centennial of the Yale Medical School, records the life and activities of one of its first professors, Dr. Nathan Smith, previously founder and for several years sole teacher of the Dartmouth Medical School, later associated with the foundation and early instruction of the medical schools of Bowdoin and the University of Vermont. It consists in considerable part of Dr. Smith's private letters, now first printed, and appropriately arranged, which reveal most intimately the character and versatile personality of this distinguished figure in New England medical history. A majority of the letters are to the late Dr. George Cheyne Shattuck, of Boston. The book is attractively illustrated with 24 full-page plates, and there is a delightful introduction by Dr. William H. Welch. An appendix records Dr. Smith's publications, and reprints in full his introductory lecture at Yale on "The Progress of Medical Science."

A Treatise on Clinical Medicine. By WILLIAM H. THOMSON, M.D., LL.D. Octavo volume of 667 pages. W. B. Saunders Company, Philadelphia and London, 1914.

The author has not aimed to produce a book of reference but rather a serviceable book for the practicing physician. In keeping with this idea the style is informal; there are exceedingly few references to the literature and much emphasis is laid on medicinal treatment. There are no illustrations. The very brief space devoted to the morbid anatomy of the various diseases impresses the reviewer as a serious drawback.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JANUARY 14, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*
WALTER L. BURRAGE, M.D. } *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D. }

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.
HARVEY CUSHING, M.D. ROBERT B. OSGOOD, M.D.
DAVID L. EDSALL, M.D. MILTON J. ROSENAU, M.D.
REID HUNT, M.D. EDWARD C. STREETER, M.D.
ROGER I. LEE, M.D. E. W. TAYLOR, M.D.

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman.*
WALTER P. BOWERS, M.D., *Clinton.*
HOMER GAGE, M.D., *Worcester.*
JOEL E. GOLDSWORTHY, M.D., *Boston.*
LYMAN A. JONES, M.D., *North Adams.*
HUGH WILLIAMS, M.D., *Boston.*
ALFRED WORCESTER, M.D., *Waltham.*
ROBERT B. OSGOOD, M.D., *Boston, Secretary.*

ERNEST GREGORY, *Manager.* W. M. LEONARD, *Consulting Manager.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

TRANSFER OF THE BOSTON QUARANTINE SERVICE.

IN the two preceding issues of the JOURNAL we have commented editorially on the proposed transfer of the Boston quarantine service from municipal to federal control. At the hearing held on this subject before the Common Council on January 1, the opposition to the proposed change was chiefly, as at the previous consideration of the subject last spring, from the shipping interests of the city. Mr. Jerome Jones, a member of the committee on maritime affairs of the Boston Chamber of Commerce, presented the following letter to Mayor Curley, representing the opinion of his committee on the subject:—

"The Committee on Maritime Affairs of the Chamber of Commerce deem it unwise, in that a change of jurisdiction would be a handicap to our port facilities, and I am not putting the question of facilities above the safeguarding of the community.

"I do not question Dr. Rupert Blue and his sincerity in doing what he can. At the same time we feel that the quarantine regulations at

the port of New York have been safeguarded in every way, and they have been lenient in allowing ships to come up from quarantine with thousands of passengers later than sunset and before sunrise; thus facilitating the landing of the passengers and making the port attractive to both steamship lines and passengers.

"We have no doubt that the first federal officials would be accommodating, but from the experience in southern ports, where the change has been made, it has been found that the boarding officials' watches are always right at sunrise and sunset, and vessels have to wait in quarantine when the many passengers are anxious to go ashore and their friends come from distances to meet them. It not only affects this port, but all of New England and trade tributary to it.

"We feel that when New York adopts the change, as it is doubtful, it will be time enough for us here, and while we respect your desire to save the city's money, it should not be done at the expense of the facilities of the port. The tidal hour has much to do with big vessels coming up to the pier, and the denial of the quarantine officer might often mean waiting 20 hours for the flood tide. Boston and New York are the two largest passenger ports on this continent, and we certainly deserve at this port equal quarantine service."

ON the other hand the proposed transfer was advocated by Mr. Sullivan, the corporation counsel, by Mr. Edward H. McSweeney, chairman of the port directors, and by Drs. H. D. Arnold, G. H. Francis and O. R. Sedgwick, representing the Suffolk and Norfolk Districts of the Massachusetts Medical Society and the Boston Homeopathic Medical Society. At a joint meeting of the executive committees of these organizations on December 22, the following resolutions were passed:—

"That the best interests of the citizens of Boston demand a reorganization of the Health Department. The plan of a Health Commissioner, as a single officer responsible for the work of the Department would, in our opinion, be the most satisfactory solution of the problem, provided he be a man of national reputation and trained in matters of public health and sanitation. The proposed salary of seventy-five hundred dollars should make it possible to secure the services of such a man.

"We therefore recommend the passage of the proposed ordinance, now under consideration by the City Council, for the reorganization of the Health Department.

"Since this ordinance provides for the establishment of a quarantine division, and since His Honor, the Mayor, has recommended the transfer of the city quarantine station to the federal service, we feel that it is appropriate to express an opinion on this matter also.

"It is our conviction that the management of the quarantine station by the federal authorities would be conducive to the better protection of the health of this city and of the country at large.

"This is a matter of the greatest importance in view of the greatly increased danger to be expected from diseases brought by immigrants after the end of the European war.

"We therefore endorse the proposition to transfer the quarantine station to the federal authorities, and recommend the amendment in this particular of the ordinance to reorganize the Health Department."

IN another part of this issue of the JOURNAL we print in full the statement prepared for presentation by Dr. Arnold to the Common Council. This may fairly be taken as representing the attitude of the Boston profession. At the time of the hearing, action by the Council was deferred, but as the decision is one of importance and must soon be made, it is desirable that physicians generally should hold and express definite views. A comparison of the arguments for and against the proposed transfer shows that the opposition to it is based on questions of business convenience and advantage. Such considerations as these are probably ill-founded, as is shown in Dr. Arnold's statement. Even if they were not, they should not be allowed to weigh in comparison with advantages of administration and the interests of the public health.

THE PRACTISE OF MEDICINE IN CHINA.

At the annual meeting of the Boston Medical Library on Tuesday Evening, January 12, Dr. Francis W. Peabody presented an interesting lantern talk on "Western Medicine in China," illustrating the advances made in the introduction of occidental medical science into the orient. Dr. Peabody speaks from recent experience, having returned but a short time ago from his work on the Rockefeller Commission in making a medical survey of China.

In this connection there is a considerable interest in the medical publications which have developed in the far east under the influence of western science. As in other matters, in the domain of medicine there is seen going on at the present time in the Celestial Empire the struggle, hard indeed, but destined to ultimate vic-

tory, of the modern and enlightened against the antiquated, ignorant and hidebound. The modern leaven is, of course, small as compared with the whole vast lump, but it is working and working powerfully. At various points there are well-equipped hospitals, medical schools, and laboratories, and there is now in China a very considerable number of European and American physicians, most of whom have had excellent professional training, while some are men of the highest scientific attainments. One of the agencies by which they make their influence felt is the *China Medical Journal*, which has just reached its twenty-ninth volume. It is published by the China Medical Missionary Association, a representative body, with branches in all the principal districts, and is a periodical which reflects great credit on that organization. One of its departments which is of special interest is that of tropical diseases. It solicits contributions from medical practitioners not only in China, but in Japan, Korea, Siam and the Philippine Islands, and many of its original articles are of great scientific value; such, for instance, as the report, in the issue for November and December, of the researches by Dr. H. E. Eggers of the Laboratory of Pathology and Bacteriology, Harvard Medical School of China, at Shanghai, on the spirochetic infection of ulcers in China.

In the same number of the *Journal* there is to be found an interesting paper by Dr. William W. Cadbury, of Canton, on "Medicine as Practised by the Chinese." While the author freely acknowledges his indebtedness to Jules Regnault's work, "Médecine et Pharmacie chez les Chinois et chez les Annanites," much of his material is the result of personal observation or derived from Chinese scholars familiar with some of the medical classics of their country. He divides medicine in China into two classes: the purely superstitious, which depends upon charms and magic, and the art of medicine as practised by the Chinese physician. In the city of Canton, he says, may be found temples dedicated to the "Spirit of Medicine," and the ignorant believe that the presiding deity will restore health upon the payment of small sums of money and the performance of certain rights. The Chinese physician, however, is a quite different individual from the Taoist priest, although magic and astrology form an important part of his armamentarium.

The practise of medicine in China is unli-

censed, and is usually hereditary, the "skilled" physician handing down his secrets to one of his sons. The study of human anatomy has been hampered by two factors: respect for the dead and the lack of any co-operation or organization among physicians. As the earth has courses of water, so man has courses in the pulse—six in number, three *yang* and three *yin*. The *yang* is the warm principle, actively flowing and symbolized by the sun; the *yin* is the moist principle, passively flowing and symbolized by shadow. If the former predominates there is excitation, and if the latter, depression of the organism; and the equilibrium of these two forces constitutes health. Six vessels carry the active principle, and six the passive, and the two spread through the whole organism by means of gases and the blood. The latter makes a complete circulation of the body about fifty times in 24 hours, passing twenty-five times through the male channels (those of the active principle) and twenty-five times through the female channels (those of the passive principle). The action of these principles depends on twelve organs and each of the organs has a canal by which it communicates with the others. Some of the communicating channels terminate in the hands, and some in the feet, and one of the vessels in the little finger is used to determine the nature of most infantile diseases. The viscera are classified under two groups, the first composed of six in which the *yang* resides, namely, the gall-bladder, stomach, small intestine, large intestine, bladder and left kidney; and the second composed of five viscera in which the *yin* resides, namely, the heart, liver, lungs and right kidney.

Auscultation and percussion are wholly unknown to the Chinese physician, and in making a diagnosis entire reliance is usually placed on the general facies of the patient and the character of the pulse. Sometimes the examination includes the tongue, and thirty-six symptoms are said to be made out from its color and the extent of its coating. The tongue and cheeks vary with the state of the heart, the tip of the nose with that of the stomach; from the general appearance of the face and nose the condition of the lungs may be determined; that of the liver by examination of the eyes and eyebrows, that of the kidneys by the ears, and that of the spleen by the mouth and lips. Each organ has its appropriate color, red corresponding to the heart, white to the lungs, black to the kidneys and bladder, yellow to the

stomach and spleen, and blue to the liver and gall-bladder. Organs also have their own peculiar times and seasons. Thus the heart, the characteristic element of which is fire, is most likely to become inflamed at noon in the summer season. Two substances are found circulating in the body,—gas and blood. The former acts upon the latter as the wind upon the sea, and the result is the production of the pulse in the vessels. More stress is laid upon examination of the pulse than anything else. Usually the physician is satisfied with palpation of the radial in both wrists, but in difficult cases examines the pulse at ten other points in the body. This method of diagnosis is carried out to the utmost refinement, with separate palpations with each finger, etc., and there are no less than twenty-seven varieties of pulse which prognosticate death. The physician must be trained to palpate the pulse so skilfully that by this sole means the nature of a disease, and even the month of gestation in a pregnant woman, may be determined.

Curiously enough, the drugs and other medications employed are weighed out according to a decimal system; but the character of the remedies themselves scarcely corresponds with this enlightened procedure. Often a prescription is given because of the resemblance of a drug to the organ affected. Thus for renal disease haricot or kidney beans are ordered; the red flowers of the hibiscus serve as emmenagogues; saffron is given for icterus. Minerals are administered as salts; plants in the form of roots, stems, leaves, flowers and dried fruits. Tigers' bones are often ground up and given to a debilitated person, and among the other animal substances made use of are the dried bodies of grasshoppers and the shell of the cicada. Impotence is treated by preparations of testicle or of nervous tissue, and diseases of the liver and eyes by pork liver. In certain districts cooked human blood is considered an excellent remedy, and at executions people may be seen collecting the criminal's blood in vessels. Pills are frequently made with a thick coating of paraffin; this is meant to be broken off, and the contents chewed up. They are generally so large that they could not be swallowed otherwise. Various forms of plasters and blisters are applied to the skin, and the actual cautery is in common use. Occasionally acupuncture is resorted to, and 388 points in the body are described as suitable for its performance. The theory on which its use is based is

that if one punctures the vessels connecting different organs the disease will become absorbed.

In the last few years two so-called charitable hospitals have been established in Canton for the treatment of the sick according to native methods, but no surgery is practised at these institutions.

THE TRANSPLANTATION OF TISSUES AND ORGANS.

THE transplantation of tissues in the human body is one of the important developments of modern surgery. Beginning with the simpler forms of skin-grafting, the process has been extended successively to fascia, tendon, bone, and even to such a delicate structure as the cornea. The possibility of transferring these tissues successfully has become of immense value in the plastic treatment of numerous bodily lesions and defects, in the repair of fractures and bone-diseases associated with loss of substance, in the mechanical remedy of certain forms of paralysis, and occasionally in the mobilization of ankylosed joints.

The transplantation of organs, as more recently developed by Carrel and various of the German surgeons, has opened new fields of surgical therapeutic opportunity, which have thus far been but partly explored. The transference of more complex structures, such as kidneys and joints, has hardly advanced beyond the experimental stage; but the possibility of transplanting intestinal segments in the plastic surgery of the vagina and urethra has been satisfactorily demonstrated. The enormous technical difficulty of such procedures will probably always restrict their performance to the hands of specialized experts. There is, however, another important group of organs, the glands of internal secretion, whose transplantation offers important prospect of benefit beyond that derived from the oral or subcutaneous administration of their extracts.

The knowledge of the endocrinous glands is again one of the valuable advances of modern medical science. Beginning with the study of thyroid secretion in the treatment of exophthalmic goitre, it has been extended to the adrenals, the parathyroids, the genital glands, and more recently, by the brilliant surgical researches of Cushing and others, to the pituitary. The complex functions and interrelations of this group

of glands form one of the latest and most fascinating chapters of physiology, and the still undetermined possibilities of their surgical and medical use hold prospect of control and cure of many serious functional aberrations and incapacities.

Among the transplantable organic tissues, one of the most commonly and easily available is the ovary. The problem of preserving ovarian tissue, both for its internal secretion and for ovulation and menstruation, is one that frequently confronts the gynecologist. Dr. Storer, in his leading article in another column of this issue of the JOURNAL, reviews the history, technic and indications of ovarian transplantation, and reports his personal work on the subject. It is a valuable contribution to recent surgical progress.

Hitherto the majority of tissue and organ transplantation has been homoplastic, within the body of the host. Heteroplastic transplants, from one individual to another, or from animal to man, thus far have but a limited field of application, being restricted to the lower, less completely differentiated tissues, like skin, bone, and tendon. This is a field, however, which contains almost limitless possibilities of research. A completed knowledge of the physiology of the glands of internal secretion, and a full development of the successful technic of both homoplastic and heteroplastic transplantation, would place important therapeutic power within the reach of medical and surgical application.

HEALTH CONDITIONS IN BOSTON IN 1914.

A PRELIMINARY report issued on January 4, by the Boston Board of Health, indicates that the death-rate in 1914 was only 15.8, the lowest in the history of the city. This gratifying result is evidence, not only of increasingly good public health conditions, but of the development of an intelligent popular interest in the limitation and eradication of disease.

The actual number of deaths in 1914, with the population numbering 766,136, was 11,808. In 1913, with the population at 750,768, the number of deaths was 11,839. Of the 11,808 deaths in 1914, 2003 were infants. In 1913 the number of infants who died was 2111. The number of

deaths from measles, scarlet fever, whooping cough and tuberculosis was less in 1914 than in 1913, the greatest decrease being with whooping cough, from which there were 97 deaths in 1913, and only 46 in 1914. Deaths from measles were reduced from 77 in 1913 to 63 in 1914; deaths from scarlet fever were reduced from 77 to 65, and deaths from pulmonary tuberculosis from 1064 to 1041. The number of deaths from typhoid fever increased from 60 to 66, and deaths from diphtheria increased from 156 to 168.

The infant mortality rate in 1914, under one year, was only 100 per thousand births, as compared with 110 in 1913 and 151 in 1903. Of the individual causes of death, tuberculosis still leads in the number of fatalities. The following table shows the comparative deaths in certain important groups during the years 1913 and 1914.

DISEASE.	1913	1914
Deaths from typhoid fever.....	60	66
Deaths from measles.....	77	63
Deaths from scarlet fever.....	77	65
Deaths from whooping cough.....	97	46
Deaths from diphtheria.....	156	168
Deaths from pulmonary tuberculosis.....	1064	1041
Deaths from cancer.....	841	875
Deaths from external causes (violence)....	873	829
Deaths of children under 1 year.....	2111	2003

In the same connection there is considerable interest in a report by Dr. Thomas F. Harrington, Director of School Hygiene, on the health conditions of pupils in the Boston public schools in 1914, showing a notable decrease in defectives during the past eight years.

"The total number of pupils now in school whose vision is not normal is 11,039, or 12.08% of the total number of pupils tested, which was 91,326. The percentage of defectives eight years ago was 31.5.

The number of pupils defective in hearing this year is 2538, or 2.8% of the total of 93,024 examined. This represents a substantial reduction of defective hearing from 8.13% eight years ago.

During the past eight years 23,655 cases of defective vision and 4806 cases of defective hearing were corrected. In the same time over 12,000 cases of obstructive adenoids and tonsils were operated on.

The statement that defective vision increases markedly as the children progress in their studies is not borne out by statistics. The percentage of defectives in the elementary and high school grades is nearly uniform, as the percentage in the elementary schools is from 10.74 to 14.70 and in the high schools 10.52 to 11.34."

AN ABSURD MEDICAL BILL.

ON Wednesday of last week, January 6, the General Court of Massachusetts convened for its annual session of 1915. Among many important pieces of medical legislation to be brought before that body during this season, is one piece of meddlesome legislation whose obvious absurdity should lead to its immediate defeat. This is a bill to regulate conditions of surgical practice in this Commonwealth. The provisions of the bill are as follows:—

"Section I. No surgeon, physician, dentist, nor other person, performing, directing or assisting at a surgical or dental operation upon a human, either on public or private property in this State, shall wear the hirsute appendages commonly known as moustache and beard.

Sect. 2. The Boards of Registration in Medicine, and of Registration in Dentistry, acting jointly, shall have full authority to prosecute violations of this act.

"Sect. 3. Violations of this act shall be punished by a fine not exceeding \$50.

"Sect. 4. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

"Sect. 5. This act shall take effect upon its passage."

The manifest absurdity of this bill requires no further comment. It might, with equal reason, require of all surgeons that the head should be shaved. Undoubtedly this proposed measure will be promptly defeated.

MEDICAL NOTES.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—At the closing session of the American Association for the Advancement of Science, at Philadelphia, on Jan. 1, Professor W. W. Campbell of the University of California, was elected president for the ensuing year.

Other officers chosen include L. C. Howard, Washington, D. C., permanent secretary; Henry Skinner, Philadelphia, general secretary; Robert M. Ogden, University of Kansas, associate secretary for the South; Albert L. Barrow, University of California, secretary of the Pacific division; and R. S. Woodward, Carnegie Institution, Washington, treasurer.

Next year's annual convention will be at Columbus, O., during the week beginning Dec. 27. A midsummer meeting will take place at San Francisco, Aug. 2 to 7.

EUROPEAN WAR FUNDS.—On Jan. 8 the total of the New York Belgian relief fund amounted

to \$783,954.00; the New York Jewish relief fund to \$282,990.00; the American Ambulance Hospital fund to \$265,006.00; and the American Polish relief fund to \$7,675.81.

On Jan. 9 the total of the New England Belgian relief fund amounted to \$168,512.52; the Massachusetts Red Cross fund to \$95,946.20; the Boston branch of the American Ambulance Hospital fund to \$50,230.45; the Boston Jewish relief fund to \$24,681.10; the New England British relief fund to \$16,418.52; the Boston Polish relief fund to \$10,917.16; and the Boston Russian relief fund to \$10,568.00.

STUDIES ON LEPROSY.—In a recent bulletin (No. 66) of the United States Public Health Service, Dr. George W. McCoy presents the 25th, 26th, and 27th of a series of studies on leprosy, being a continuation of the important work in this subject begun in 1908, by the United States Public Health Service. The present communication deals with studies in immunity in leprosy, with the cultivation of acid-fast bacilli from lepers by the use of symbiotic organisms, and with a statistic study of leprosy in Hawaii. The author finds that the serum of but few lepers agglutinates any acid-fast cultures, and serologic methods are of chief value in making group classifications of such bacilli. Immunization of rabbits with leprosy material does not yield agglutinins for acid-fast cultures. The cultivation of these acid-fast organisms is best made by the use of symbiants.

THE SANITATION OF IQUITOS.—In a recently published reprint (No. 233), Dr. G. M. Converse of the United States Public Health Service, describes a recent sanitary campaign for the improvement of public health in Iquitos, a Peruvian port twenty-three hundred miles from the mouth of the Amazon River and only four degrees south of the Equator. Its average temperature is about 86° F. and it has a high humidity and rainfall. The population consists of about twelve thousand inhabitants, mostly Indians. There is no public water supply, no sewerage system and no local hospital. During the ten years from 1903 to 1913, this town had an average mortality of 40.5 per thousand, increasing to an average of 46.5 from 1910 to 1913, and 49.5 in 1912. The principal work undertaken by the author was the eradication of yellow fever and intestinal parasites, the chief cause of death and disease among the natives. This was accomplished by the regular sanitary methods, and in 1913 the death-rate fell to 28.8 per thousand and in the first half of 1914 to 21. This report presents a striking example of what may be accomplished in the improvement of local sanitary conditions by the application of simple hygienic methods rigorously enforced.

NEW YEAR BEGINS WITH LOW DEATH-RATE IN NEW YORK.—The new year has opened with a

slightly lower death-rate than that of the first week of 1914, the rate for the two weeks under comparison being 14.30 and 14.43, respectively, a decrease of .13 of a point, which is equivalent to a relative decrease of 14 deaths.

The most noteworthy feature of mortality for the week just passed was the considerable increase in the number of deaths charged to pneumonia, there having been 277 deaths reported during the week, as against 225 during the first week of 1914. The increase in the deaths from broncho-pneumonia was distributed among the children at the early ages, while that from lobar pneumonia was distributed among the age group between five and sixty-five years.

The total number of the deaths from infectious and contagious diseases, measles, scarlet fever, diphtheria and croup, whooping cough, typhoid fever, cerebrospinal meningitis and diarrheal diseases was considerably below that of last year.

HARVEY LECTURE.—The sixth lecture, in the current course before the Harvey Society, will be given at the New York Academy of Medicine on Saturday evening of this week, Jan. 16, by Dr. Edward R. Baldwin, of the Adirondack Cottage Sanatorium, on "Immunity in Tuberculosis, with Special Reference to Racial and Clinical Manifestations."

THE CORONER SYSTEM IN NEW YORK.—On Jan. 4, Leonard M. Wallstein, New York commissioner of accounts, filed with Mayor Mitchel a report recommending the abolition of the present coroner system in New York City and the substitution therefor of the system of medical examiners as it exists in Massachusetts.

By examination of nearly four hundred witnesses, the report says, it has been found that "the elective coroner in New York City represents a combination of power, obscurity and irresponsibility which has resulted in inefficiency and malfeasance in the administration of the office"; that of the sixty-five coroners who have held office since consolidation, not one was thoroughly qualified for the adequate performance of his duties; that the incompetent medical work of the coroner's physicians deprives the community of an absolutely necessary deterrent to crime; that because of this fact numerous homicides have undoubtedly failed of detection, and infanticide and skillful poisoning can be carried on almost with impunity so far as the coroner's office is concerned; that coroners' juries have been packed with friends of the defendants appearing before them; that coroners have abused their powers to compel the employment of favored undertakers, attempts have been made to extort money from insurance companies in return for findings in the interest of the companies, and many other forms of petty graft and abuses have been practised. The report urges that the jury system and the coroners' court be

eliminated, the responsibility for criminal investigations be given completely to the district attorney and the police, and the new medical board be composed of experienced pathologists, the chief of whom should be appointed by the mayor as the result of a non-assembled competitive examination.

BOSTON AND NEW ENGLAND.

MEASLES IN STURBRIDGE.—Report from Sturbridge, Mass., on Dec. 31, states that there were then 30 cases of measles in that town, 13 being in one family.

WORK OF MILK AND BABY HYGIENE ASSOCIATION.—The recently issued annual statement of the Boston Milk and Baby Hygiene Association shows that during the year 1914, a total of 4108 babies under one year of age were cared for by the institution.

OPENING OF THE CARTER MEMORIAL HOSPITAL.—On Jan. 1, 1915, the new Carter Memorial Hospital, at Lancaster, Mass., was formally opened, and its keys presented to the trustees of the Clinton Hospital Association. Dr. Walter P. Bowers, of Clinton, presided, and addresses were made by Governor Walsh and others. On Jan. 2 the hospital was opened to public inspection. It is a local institution for the treatment of tuberculosis.

MENINGITIS, PELLAGRA, AND POLIOMYELITIS IN MASSACHUSETTS.—During the month of November, 1914, 11 cases of cerebrospinal meningitis were reported in Massachusetts, 6 being in Boston. During the same month, 9 cases of poliomyelitis were reported in Massachusetts, and 16 in Virginia; 3 cases of pellagra in Massachusetts and 28 in Virginia.

CONVICTION OF A VERMONT DRUGGIST.—In the issue of the JOURNAL for Dec. 3, 1914, we noted the death of 14 persons in Vermont from poisoning by whiskey adulterated with methyl alcohol. The druggist who sold this whiskey has been tried, convicted of manslaughter, and sentenced to 12 or 15 years' imprisonment.

NOTIFICATION OF DEFICIENCIES IN WATER SUPPLY.—The following circular letter was sent on Dec. 31, 1914, by the State Commissioner of Health of Massachusetts, to the local health boards of such towns in this Commonwealth as are dependent on sources of water supply likely to become depleted during the present drought:

"At the present time, on account of the deficient rainfall of the past few months, many wells that are used for domestic water supply are dry and small reservoirs have become considerably depleted. While these conditions are not

extraordinary, they are more serious than have occurred at this time of year for three or four years and, while public water supplies, except those drawn from streams having little storage, are as yet not greatly affected as a rule by these conditions, the private supplies derived from wells, springs, etc., in villages and on farms have in many cases become exhausted and water is being drawn from sources not commonly used.

"In view of these conditions, it is advisable to warn the public, especially that part of it that is supplied with water from private sources, of the dangers of typhoid fever and other diarrheal diseases to which they may be exposed by the taking of water from unusual sources. They should be warned to look carefully to the possible impurity of such sources and to protect themselves against danger of infection, if the source used appears in any way doubtful, by boiling the water before using it for drinking. Especial care should also be taken by physicians to report promptly all suspected cases of typhoid fever and dysentery (winter cholera) to the proper officers.

"In cases where a citizen of a town is in doubt as to the safety of any temporary water supply which he may propose to use, he should apply to the local board of health of the town for advice. If it should happen that any city, town, water or aqueduct company finds itself short of water, or in danger of a shortage, it should apply at once to the State Department of Health for advice as to an additional supply, unless such action has already been taken.

A. J. McLAUGHLIN,
Commissioner of Health.

ADMISSION REQUIREMENTS TO HARVARD MEDICAL SCHOOL.—New requirements for admission to the Harvard Medical School, proposed by the faculty of medicine, have been accepted by the college corporation. Hereafter, candidates may be admitted to the medical school on the following terms:—

"Graduates in arts or science of approved colleges or scientific schools who can furnish evidence (a) that they have such a knowledge of physics, of biology, of general chemistry and of organic chemistry as may be obtained from one year's course in each of these subjects as given in approved colleges and scientific schools; (b) that they have a reading knowledge of French or German.

"Students who have completed two years of work in a college or scientific school of high rank, provided they present certificates: (1) that they have stood in the upper third of their class; (2) that one year's course has been taken in physics, in biology, and in general chemistry and in organic chemistry, and (3) that they have a reading knowledge of German or French."

AN IMPORTANT MEDICAL BEQUEST.—The will of the late Dr. William H. Baker, of Waltham,

Mass., which was filed on Jan. 2 in the probate court at East Cambridge, Mass., contains a bequest of \$50,000 to the Harvard Medical School to endow a professorship of gynecology, on condition that the chair shall be separate from those of surgery and obstetrics. In case the gift should not be accepted on these terms, the fund reverts to the Free Hospital for Women, Brookline, Mass.

HOSPITAL BEQUESTS.—The will of the late Dr. Edward R. Cogswell, of Cambridge, Mass., who died on Dec. 22, 1914, was filed on Jan. 1, 1915, in the probate court at East Cambridge, Mass. It contains a bequest of \$2000 to the Cambridge Hospital.

The will of the late Rebecca H. Hobbs, of Waltham, Mass., which was filed in the probate court at East Cambridge, Mass., on Dec. 31, 1914, contains bequests of \$5000 to the Waltham Hospital, \$1000 each to the Waltham Training School for Nurses, and the Waltham Baby Hospital, and \$500 to the Waltham District Nurses' Association.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Jan. 5, 1915: Diphtheria, 49, of which 4 were non-residents; scarlatina, 52, of which 7 were non-residents; typhoid fever, 6; measles, 94, of which 1 was non-resident; tuberculosis, 36, of which 2 were non-residents. The death-rate of the reported deaths for the week was 19.06.

2. Chute does not go into the technic of radical operation, but rather devotes his paper to the reasons for such procedure, speaking especially for the more thorough removal of diseased lymphatics.

3. Squier in his paper devotes himself almost entirely to the description of the technic of subtotal cystectomy.

4. Skillern has an extremely interesting article on minute bone cysts of the metacarpal bones, which is worth reading.

6. Barney's paper gives figures of much interest and importance. He finds that tuberculosis of the genital tract is accompanied by old or active lesions in other organs in more than 55% of cases, most of them being in the lung. The genital tract is usually first attacked in cases of genito-urinary tuberculosis.

Over 27% of 113 patients traced died of some form of tuberculosis. Miliary, renal and lung tuberculosis, in order, are the prevailing types of the disease. Barney believes that until ten years have elapsed after operation, no patient can be said to be cured of this form of tuberculosis. In genital tuberculosis, neither the disease nor the operation for its relief seems to impair masculinity. Experience shows that although the prostate and seminal vesicles are involved in most cases of epididymal tuberculosis, this condition will improve or heal after removal of the epididymis. Radical surgical treatment of these organs is unnecessary and unwise.

7. These authors make the emphatic statement that, as compared with salvarsan, neosalvarsan is a comparatively inert drug and its use should be abandoned in favor of the former if we wish to do our patients justice. They state that four injections of salvarsan combined with intensive mercurial treatment give nearly twice as many negative serum reactions as do five injections of neosalvarsan with mercury. The ratio is 64 to 33.3%.

10. Ritter believes that a sputum lymphocytosis showing under the microscope 50% or more of the small mononuclear leucocytes with a moderate amount of albumen by chemical test speaks very strongly for the presence of a pulmonary tuberculosis. In pre-incident or incipient cases of pulmonary tuberculosis a lymphocytic sputum is usually present, with a greater or lesser albumen content; in this the tubercle bacillus may be entirely absent or only occasionally found. The presence of the mononuclear lymphocyte in the sputum in preponderant amounts and a positive albumin test is simply the forerunner or near the beginning of positive findings, for the tubercle bacillus, if not already present in the sputum, will soon be found. 3. Capps and Davis report a study of an epidemic of 348 cases of streptococcus sore throat which occurred in Jacksonville, Ill., in the winter of 1913-14. The epidemic was traced to the milk of cows affected with streptococcus mastitis. The streptococci in the milk were found to have hemolytic properties. They did not multiply appreciably at room temperatures because of the inhibiting influence of other milk bac-

teria. They were soon killed by the acidity of sour milk or buttermilk and died out in ordinary butter in a few days. They lived in ice cream for at least three weeks without appreciable loss of numbers or virulence. There was good reason to believe that in this epidemic ice cream played an important rôle as a carrier.

4. Gay and Claypole advocate the testing of typhoid immunity by means of an artificial typhoid-carrier state in the rabbit, and describe their technic. Their experiments show that untreated bacteria, killed and precipitated by alcohol, dried, ground and weighed, do not protect so well as typhoid bacilli that have been sensitized by an immune serum and subsequently treated in the same manner. The sediment of unsensitized bacterial bodies freed from the supernatant, endotoxic fluid contains the immunizing principle almost in its entirety. Alcohol-killed, sensitized cultures protect almost as well as living sensitized cultures, and the sediment of the former better than the living cultures. These sensitized cultures produce a more durable type of immunity and cause less reaction, both local and general. For prophylactic immunization the writers recommend three injections at two-day intervals of such a culture, perfectly polyvalent, in the dose of 3/32 mg. of the original dried culture, which corresponds approximately to 750 million living typhoid bacilli. They consider the skin test with the typhoid solution of far more value than the agglutination reaction with immunized serum as an index of the degree of protection.

7. Hamburger and Friedman conclude from experiments on dogs that pyloric obstruction with resulting motor insufficiency and continuous secretion is probably the most important factor in the production of chronic experimental ulcer. It is probable that in man primary partial pyloric stenosis (from whatever cause) with secondary motor insufficiency and continuous secretion is largely responsible for the progression and delayed healing of chronic ulcer.

8. Levy and Strauss report a study of hexamethylenamin as a urinary antiseptic. They find that in neutral solutions in concentrations up to 1:10 it is neither inhibitory nor bactericidal. Given in doses of 7½ grains three times a day, it is broken down into formaldehyde in all acid urines. Formaldehyde is formed in the bladder in all cases except in those in which the acidity of the urine is higher than normal. In these cases some formaldehyde is formed in the kidneys. With a dose of 7 grains of hexamethylenamin three times a day formaldehyde is never present in concentrations greater than 1:5000. The only organism which is destroyed or whose growth is inhibited by this concentration is the typhoid bacillus. For the destruction or inhibition of other organisms a high acidity is necessary and such high acidity in combination with the formaldehyde may injure the kidney tissue. Hexamethylenamin is undeniably efficacious in typhoid fever for the prevention of pyelitis and cystitis.

9. Webb, Gilbert and Havens studied the blood-platelets in tuberculosis in man and in guinea-pigs. They found the platelets consistently increased in number. A change in altitude from sea-level to 6000 feet increased the number of platelets 12%. Their experiments indicate that the platelets either contain or supply opsonin, and that when added to a lethal dose of tubercle bacilli they either prevent infection or modify its course. The addition of serum to a mixture of blood platelets and tubercle bacilli appears to interfere with this modification. [L. D. C.]

DEUTSCHE MEDIZINISCHE WOCHENSCHRIFT.

No. 38. SEPTEMBER 17, 1914.

1. v. HANSEMAN, D. *The Cancer Problem.*
2. *RISEL. *The Diagnosis of Smallpox.*
3. *GLASER, F. *Salvarsan in Scarlet Fever.*
4. LETHAUS. *Sciatica Treated by Nerve Injections.*
5. KORR, P. *Iod-prothacmin.*

2. Risel states that small-pox, typically, has an incubation period of about twelve days. This is followed by a pro-dromal period of three days, characterized by a sudden onset of fever, malaise and vomiting. These symptoms subside with the appearance of the smallpox eruption. The rash is very diffuse and is seen over the entire body but may be most abundant on the exposed surfaces. It is first papular, but rapidly becomes vesicular and pustular. It tends to involve the deeper layers of the skin. The blood shows a leucocytosis with marked increase in the large mononuclear cells. In the most severe and acutely fatal cases of smallpox, the eruption may have a hemorrhagic character. The true rash may be preceded by a diffuse and transitory erythema or purpura.

Chicken-pox is the disease most likely to be confused with smallpox. In this the skin lesions are more superficial, and all stages from papules to pustules are seen at the same time. The rash is less thickly distributed on the extremities and more thickly over the abdomen. The characteristic leucocytosis is absent.

Finally, animal inoculation may be used for differential diagnosis. Subcutaneous injections into rabbits of serum from the chickenpox vesicle will produce no reaction, while the serum from a smallpox vesicle will produce characteristic lesions. This procedure, however, takes a few days, and thus is not particularly valuable.

3. Glaser has treated scarlet-fever with salvarsan because a positive Wassermann reaction has been found in various cases at the height of the disease, on account of the beneficial action of the drug in certain ulcerative forms of tonsillitis, and because of its good effect on many protozoan diseases, of which scarlet fever may be one.

Glaser reports a series of 42 cases, including severe cases, and mild cases. His results show that salvarsan had no effect in the most severe cases. In others, the fever and mental confusion were often relieved after the drug was injected. The various complications of scarlet fever were not influenced by the treatment. A diphtheroid membrane, if present, seemed to clear up more readily. Chills, vomiting, or diarrhea appeared in over one-half the cases following injection. [R. F.]

10. OBENDÖRFFER, E. *Letters from the Battle Front.*

1. Bonhoeffer feels that under the physical and physical stress of war, individuals with a predisposition to mental instability become diseased more readily than under normal conditions. The symptoms of such disturbance may take the form of phobias or hallucinations so that a soldier becomes dangerous to himself and his companions, and tends to render military discipline difficult to enforce. Or the symptoms may occur as paralyses or convulsions, developing during a disease. Dementia precox and dementia paralytica, too, seem to develop more readily among fighting soldiers. Therefore Bonhoeffer believes that men who are subject to neuroses should be considered unfit for military duties. Those sol-

diers who develop signs of mental disturbance should be sent from the firing line at once, or if this is impossible should be quieted with hypnotics.

4. Boeters has treated a series of cases of gonorrhea and its complications with intravenous or intramuscular injections of a proprietary vaccine sold under the name of Arthigonin. He believes that vaccine therapy is of great value in local gonorrheal infections (prostatitis, epididymitis, parametritis, etc.), and also in metastatic lesions. Arthigonin is of value in diagnosis on account of the general reaction obtained in specific cases following its injection.

17. NOBLING. *Concerning Wounds of the Bladder.*
18. MÜHLENS. *Typhus and Relapsing Fever.*

1. Several illustrations with good descriptions are given showing various techniques which are of use in localizing foreign bodies in the skull and trunk and limbs.

3. Pöhlman gives in detail the case of a man infected with syphilis 36 years previously and having definite signs and symptoms of tabes dorsalis who

presented himself for treatment with a primary lesion typical in every diagnostic point except that spirochetæ were not looked for. The incubation period, course of the lesion and reaction to mercury and salvarsan were characteristic. Pöhlman believes it to be a fresh infection on top of an old infection.

7. Gas gangrene: If there is a pure infection of the gas bacillus no suppuration takes place and the only sure way of differentiating from malignant edema is by animal inoculation which takes from 12 to 18 hours. Staining is also fairly accurate as the differences between the gas bacillus, anthrax and the germ of malignant edema are well marked. The treatment consists first in getting oxygen into the tissues by means of free incisions, oxygen and hydrogen peroxide. Amputation may be best. The patient's strength must be kept up.

13. Euricke is not favorably impressed with the use of magnesium sulphate: He used it on eight cases with poor success as the sickest cases were little if any influenced. He gave an intradural injection of 10 c.c. of 10% sol. and 8 c.c. three days later. He insists that it can never take the place of the serum.

[E. L. Y., Jr.]

BULLETTINO DELLE SCIENZE MEDICHE.

2. *BONOLA, F. *Contribution to the Study of the Grey Commissure of the Thalamencephalon.*
3. CAVINA, G. *An Interesting Case of Cardiophtosis.*

2. As a result of his anatomic investigations, Bonola concludes that the grey commissure of the thalamencephalon in man is the rudiment of a commissural nucleus analogous to the nucleus of the median line in the lower animals. In phylogenesis this nucleus has become involuted until it has reached the low development in the human species, and in ontogenesis also it has undergone important involutionary modifications.

[R. M. G.]

Miscellany.

THE TRANSFER OF THE QUARANTINE STATION.*

MODERN maritime quarantine is not a matter of solely local character and importance, on account of the fact that large numbers of persons are in transit through the ports of entry to various places throughout the whole country. Only a relatively small proportion of immigrants landing here remain in Boston. It is as much a matter of national concern as the immigration service, or the coast defenses. The expense of an adequate quarantine service should be borne by the National Government and not by the City.

Uniformity of quarantine regulations and of quarantine procedure throughout the ports of the country are desirable, not only for the protection of the health of the people, but in the interest of commerce.

It is to the advantage of the shipping interests to have only one set of regulations to meet in the various ports of the country—the minimum

* A statement prepared for presentation by Dr. H. D. Arnold before the Boston Common Council.

regulations prescribed by national law. Local boards must live up to these requirements—but they may impose additional restrictions. Where the local and national services both exist at the same port, there is danger of conflict and confusion, and of consequent delay.

If the quarantine is under federal administration, the quarantine work and the inspection of immigrants—administered by the same department of the public service—can be carried out as efficiently as at present, yet with a saving of time.

It is believed that in the long run federal control of quarantine will be fully as acceptable to the shipping interests as local control. This has been the experience where this system has been adopted.

The advantage is still greater in times of danger, when it is known that quarantinable diseases exist at ports from which vessels come, or in countries from which the immigrants come. Such information is reported promptly to the Public Health Service, either through its own agents or the representatives of the Department of State. If the Public Health Service has control of quarantine, the necessary measures for protection—which it would enforce any way—can be taken without delay, and can be arranged so as to cause the least possible delay and inconvenience to shipping that is compatible with safety. Under such conditions of danger, not only would the direct control of quarantine by the Federal Government be of advantage to the shipping interests, but it would better guard the health of the country. One organization, which can inspect abroad at the ports of departure, and again at the ports of entry, and which has authority to follow cases over the country, must be more efficient than if an independent body is interposed as the middle link of this chain.

Such conditions of danger we must face in the near future. This is the opinion of the medical profession, of the Public Health Service, and of all who have given serious thought to the situation. This is due to the European war.

Proper hygienic measures are impossible under the conditions in which the vast armies are fighting. The medical service is inadequate. Typhoid fever is prevalent. It is reliably reported that cases of cholera have occurred, and we know this disease became prevalent in the Balkan war. We recall the ravages of the plague in Manchuria during the Russo-Japanese war, and there is danger of the introduction of this disease through the Russian army. It will be a miracle if Europe is not involved in epidemics of these diseases before the war ends. And soon after we shall have hordes of immigrants from the infected regions.

Cholera and plague are the two diseases most to be dreaded—and expected through the war. The danger from smallpox coming from Southern Europe will be increased. The most efficient protection is none too good. Federal control is

better than local control under these circumstances—in fact, it cannot be avoided.

If we grant, for the sake of argument, that the shipping interests might enjoy certain temporary advantages if the quarantine remains for a time longer under local control, they would lose much more in the apparently inevitable control by the Federal Government when we face these dangers in the near future. The change in the face of danger would mean serious delay in establishing an effective organization,—which could now be inaugurated without inconvenience.

Should cases of cholera or plague reach this port, and gain a foothold through ineffective preparation, the loss to the shipping interests would be enormous; and the expense to this community in eradicating these diseases would be immense. We have only to cite the recent experiences of New Orleans and San Francisco to enforce this lesson.

It is recognized that under the ordinary conditions of the past our local quarantine service has been efficient. It can hardly be claimed, however, that its officers have had as good experience as those available in the Public Health Service have had, in dealing with emergencies of the kind expected. Furthermore, the equipment of our quarantine station is entirely inadequate to deal properly with such emergencies.

It is folly to wait until the emergency is upon us, that is, if we have any regard for the commerce of this port. What commerce needs is a station not only to accommodate persons who are actually sick, but to provide properly for those who are well and must be detained for observation. A steamer should be able to discharge its passengers at once, be disinfected, and proceed with the least possible delay. Anything less than that means serious financial loss. Proper equipment of this station cannot begin too soon. It means a large expenditure—perhaps more than a hundred thousand dollars. The National Government is ready to take up this problem and undertake the proper development of this station. The citizens of Boston should not be called upon to bear this expense. Yet, unless we surrender the quarantine to federal control, we must undertake this work ourselves or we recklessly endanger our health and the business interests of the whole community.

Hitherto the shipping interests of this port have opposed the transfer of quarantine from local to federal control. The medical profession is unwilling to believe that they would urge their own interests at the expense of the welfare of this whole community; and it concludes that they cannot have had a realizing sense of the dangers that are so apparent to medical men in the near future.

I understand that the shipping interests have maintained that they would be subjected to restricted hours of service and to delay through appeals to Washington, which they would not be subjected to by local authorities.

I am assured by Surgeon-General Blue, of the Public Health Service, in answer to my direct questions, that:—

Under Federal control of quarantine, the convenience of vessels as to time of examination will receive as much consideration as has been given by the local authorities, and that there will not be any stricter enforcement of regulations about hours of quarantine.

The officer in charge of the Boston quarantine station, if it should be transferred, would have as absolute authority as possible; and the result, as far as concerns possible appeals, would be as fully as satisfactory as at present.

This is the fixed policy of the Department, and is not dependent upon the individual in charge at any given time.

It has also been urged, I believe, that Boston should not make this change until it is also made in New York and Baltimore—rival ports. It is difficult to understand wherein the advantage of local control would lie, under the above guarantees, because it is expressly stated that the local service does not give any advantage by lax regulations, but only by a willingness to be accommodating. Even if it were true that some slight advantage to shipping interests lies in local control, when quarantine conditions remain as quiet as in the past, we must look ahead and consider the interests of this port. We are almost sure in the near future to be obliged to meet conditions of danger, in which the Federal Government will feel obliged to step in and exert its authority. With the inadequate provisions of our station, Boston, as a port, would suffer seriously in competition with these other ports.

For the above reasons we earnestly urge the City Council to authorize at the present time the transfer of the Boston quarantine station to the control of the Federal Government. In addition, it would seem probable that the shipping interests would receive more coöperation, if we thus meet the wishes of the National Government in its plans to protect the country against the importation of disease.

BRITISH RED CROSS HOSPITALS.

THE following details of the British Red Cross Hospitals at Calais and Dunkirk appeared in a recent issue of the *British Medical Journal*:

“It seems sometimes to be assumed in England that Calais and Dunkirk are British hospital bases. This is not the case; neither of them is occupied by the British forces, and our own Army Medical Service exercises no control over the medical arrangements existing therein. It occasionally happens that a British soldier gets included in a batch of French or Belgian wounded, and is taken to one of these towns for

treatment, and since these towns are not far removed from the British lines, unsanitary conditions in them, or rather, the existence of a considerable amount of epidemic disease, might complicate matters for our own army authorities. These towns have, however, a direct interest for the British public, owing to the fact that there are established within them an aggregate of about ten voluntary hospitals of British origin. For the most part they are working under the nominal control of the French or Belgian authorities, but at one time and another nearly all of them have received more or less extensive assistance from or through the British Red Cross Society itself, and still require it. Moreover, the ambulance work connected with those at Dunkirk is under the direct control of this Society.

"Of the two hospitals at Calais, one is concerned with the special arrangements proposed for the benefit of the Belgians suffering from typhoid fever. I am unable to describe it more precisely, for at the time of my last visit to Calais it was not complete. The other hospital has been at work for some weeks. It owes its foundation, I understand, to a subscription got up in the Baltic Exchange in London, and is fortunate in having its nursing arrangements in the hands of a lady who, at the time of her appointment, had only recently returned from a long tour of corresponding work in the Balkans. This hospital, which ranks as a British Red Cross institution, shares the Sophie Berthelot School—a very large building—with a French Red Cross hospital, and can accommodate 80 or 90 Belgian wounded. A third extemporized institution in the town should also be mentioned, though except for the fact that most of its nurses have been supplied by the British Red Cross Society, I do not know that it can be regarded as in any wise British. This is the Jeanne d'Arc Hospital. It is under the control of Professor Depage, whose chief assistant is Dr. J. van de Velde, and is doing some very admirable surgical work.

"Of the seven hospitals in Dunkirk, much the largest is that known as the Duchess of Sutherland's Hospital. It has about 70 beds, and, under the very active control of Millicent Duchess of Sutherland herself, has been leading a useful if somewhat ambulatory existence almost since the beginning of the war. Another—and one of the youngest—is supported by the Quaker community, and is apparently very well organized. A third, which represents Edinburgh and the Border towns, has a very strong staff, but seems to be badly off for funds—a malady from which most of the hospitals in Dunkirk appear to suffer. As they are all quite small institutions, and with one exception are all housed in rather flimsy buildings of the summer residence order, it is possible that their common object would be better attained if a process of amalgamation were carried out. That object is the benefit of the French wounded, and its desir-

bility is not in the least diminished by the fact that the principle on which the French medical authorities are working is that of evacuating to his own territorial area every wounded man who can possibly be moved. It might be well if the small committee which represents them with the French authorities besides bringing about one or more amalgamations, were strengthened by the inclusion of a larger French official element.

"The voluntary hospitals at British bases, such as Boulogne, Rouen, Paris, and Havre, are in a different position; they all work under the general authority of Sir Arthur Sloggett in his double capacity of Director-General of the Army Medical Service (overseas) and of Chief Commissioner of the British Red Cross Society and St. John Ambulance Association. As the operations of the British Red Cross Society in France now extend over so wide a field, and it is obvious that they will have to be continued for a very long period, it seems to be thought best that general administrative control should be placed in the hands of someone accustomed to the management of large commercial undertakings."

MASSACHUSETTS SOCIETY FOR MENTAL HYGIENE.

THE Massachusetts Society for Mental Hygiene, an organization recently formed in this state, has issued as its first publication a report stating its aims and purposes, the following quotations from which indicate the field in which the society purposes to work:—

"During the fiscal year ending Nov. 30, 1913, there were admitted to the various State hospitals 5007 patients. During the same period there were under care in the various hospitals 889 epileptics, 1444 inebriates, 18,971 insane (including those in private hospitals), making a grand total for feeble-minded, epileptic, inebriate and insane under care during the year, of 24,005. The hospitals spent during the year \$4,264,919.71, which sum was more than one-quarter of the State's total expenses for the year.

"These figures, impressive in size though they are, obviously do not represent the whole number of persons affected, since, with few exceptions, each patient represents a family; nor the total cost, since to the above must be added the cost of rearing and educating those who become incapacitated through mental disease, the loss in earning capacity, etc.

"If all this were unavoidable, it would be well to say little. But much of it is avoidable. Many of the forms of mental disease are subject to control just as are tuberculosis, typhoid fever, or smallpox. Each of the three great causes producing the above toll is fundamentally preventable. The problems asso-

iated with them are admittedly numerous and intricate, but the fact remains that they are the producers of the great majority of mental diseases, and unnecessarily so. The society aims to educate the people as to the real causes of mental disease and to instruct the general public in plain and tested measures for preventing disease.

"The society proposes to provide competent speakers to address groups in any part of the state, on the causes and prevention of mental disease; to distribute such pamphlets and leaflets as will interest and inform the general public; to familiarize the public with the methods used by the state in the care and treatment of mental cases; to maintain for general use a collection of literature on the subject of mental disease and its prevention, together with information in regard to progress made in other states and communities in the care and treatment of mental cases; to furnish information to physicians, social workers and others, as to the public facilities for the diagnosis, care and treatment of mental cases, and as to the laws, rules and practice in regard to availing themselves of these facilities; to study, so far as time and funds will permit, and to stimulate others to study, the different phases of the problem of mental hygiene, and to publish the results of such studies."

The officers of the society are: President, Judge Harvey H. Baker; vice-president, Dr. Walter E. Fernald; secretary, Dr. Charles E. Thompson; treasurer, John Koren; executive secretary, Dr. Frankwood E. Williams.

Among the directors are: Pres. Eliot, Dr. James J. Putnam, Dr. Alfred E. P. Rockwell, Worcester; Miss Edith N. Burleigh, Dr. Henry C. Stedman, Prof. Robert M. Yerkes, Dr. George C. Tuttle, Waverley; Rev. Michael J. Scanlan, Dr. Everett Flood, Monson; Bishop Lawrence, Frank L. Randall, Dr. Walter Channing, Supt. Ayer, Robert A. Woods, Dr. Ernest V. Scribner, Worcester; Edwin Mulready, Dr. E. E. Southard, Pres. Butterfield, Amherst; Dr. Irwin H. Jeff, Norfolk; Dr. John A. Houston, Northampton; Dr. Herbert B. Howard, W. Murray Crane, Dalton; and David Snedden.

THE FRENCH BIRTH-RATE.

THE following data about the diminishing French birth-rate were published in the issue of the *Lancet* for Dec. 12, 1914:—

"The diminishing birth-rate, disquieting as it always is, is more so at the present time, when it has so important a bearing on events. The births fell from 750,651 living children in 1912 to 45,539 in 1913. So low a figure had never been recorded, with the exception of 1911, when it was regarded as deplorable. To estimate the lamentable and continued shrinkage of the French

birth-rate it suffices to recall that the annual mean of living births was 945,000 during the period 1872 to 1875, that since 1907 the number of births has fallen below 800,000, and since 1911 below 750,000. That is to say, that in less than 40 years the births in France have diminished by 200,000 a year. The proportion of living children notified to 10,000 inhabitants was 188 in 1913, as against 190 in 1912, 187 in 1911, 196 in 1910, and 205 in 1906. The shrinkage increases year by year. It is true that in all the great countries of Europe the birth-rate is decreasing, but in a much less degree than in France, and, moreover, the annual excess of births over deaths is proportionately from six to ten times greater than in France. Thus, for 1912 the excess of births over deaths per 10,000 inhabitants was in France only 15. In the same year it was in the Low Countries 158, in Italy 140, in Hungary 130, in the German Empire 127, in Austria 107, and in England 105. Last year the excess was 41,901 births, or only 10 per 10,000 inhabitants. The excess of 1912 was 57,911, or 15 per 10,000. There has thus been a diminution of one-third. This diminution springs from a simultaneous deficit of 5112 births and an increase of 10,898 deaths. Last year an excess in births was noted in 49 departments in place of in 56 in 1912. The departments in which the birth-rate exceeds the mortality are those of the Nord, Pas de Calais, Bretagne, the frontier regions of the North-Est, Limousin, and Corsica. On the other hand, Normandy and Dauphiny continue to depopulate. The proportion of births per 10,000 inhabitants was 196, as against 198 in 1912. The departments in which the birth-rate was highest were Pas de Calais, 266 children per 10,000 inhabitants; Finistère, 259; Morbihan, 248; Seine Inférieure, 240; Meuthe and Moselle, 239; Côtes du Nord, 236; Lozère, 219; Doubs, 217; Nord, 216; Mayenne, 213; Vendée, 211; and Vosges, 210. Those in which it was lowest are the Valley of the Garonne and Bourgogne; Gers, 129; Lot et Garonne, 134; Yonne, 137; Nièvre, 141; Allier, 143; Lot, 145; Haute Garonne, 147; Gironde, 148; and Ariège, 149. The number of deaths, 703,638 (stillbirths 31,119, excluded) is greater by nearly 11,000 than that of 1912, which was the lowest recorded since the beginning of the present century. The ratio of deaths for the entire population was 178 per 10,000 inhabitants, as against 172 in 1912, 196 in 1911, and 179 in 1910. The death-rate has risen in 64 departments, and particularly in the Bouches du Rhône, the Dordogne, the Var, Haute Savoie, Corsica, the Somme, Haute Vienne, Aveyron, and Tarn-et-Garonne. The Norman and Breton departments continue among those furnishing the largest proportion of deaths."

The phenomena of the French birth-rate are not only of the greatest sociologic significance, but have added importance in view of the possibility of a long continuance of the European war and the imperative need of constant reinforcements.

BELGIAN PHYSICIANS' RELIEF FUND.

The following is the report of the Treasurer of the Committee of American Physicians for the Relief of the Belgian Profession for the week ending January 2, 1915.

Contributions:

H. F. W.	\$ 25.00
B. C.	2.50
D. W. C.	25.00
V. P. G.	25.00
Mrs. J. B. M.	100.00
E. F. B.	5.00
C. W. N.	25.00
In Memory H. H. C.	10.00
S. J. M.	15.00
D. B.	25.00

Total\$257.50

Disbursement None

Contributions previously reported. 405.00

Grand total\$662.50

The following local contributions are also gratefully acknowledged:

Dr. David W. Cheever	\$25.00
In Memory of H. H. C.	10.00
Dr. E. S. Boland	5.00
Dr. F. W. Stetson	10.00
Dr. Henry M. Swift	10.00

\$60.00

NOTICES.

Physicians visiting the city will be cordially welcomed at the following clinics on the days and hours specified.

THE BOSTON CITY HOSPITAL.—After January 1, 1915, public operations will be performed in the Surgical Amphitheatre each week, on Thursdays, Fridays and Saturdays, at 10 o'clock.

Thursday: First Surgical Service. Dr. Blake.

Friday: Third Surgical Service. Dr. Nichols, and Fourth Surgical (G-U) Service. Dr. Thorndike.

Saturday: Second Surgical Service. Dr. Lund.

Notice of these operations will be sent to anyone expressing his desire to receive it.

MASSACHUSETTS GENERAL HOSPITAL.—1. A surgical clinic Tuesday, at 12, in the out-patient amphitheatre. 2. Operations in the Bigelow amphitheatre Saturdays from ten to one. 3. Operations in the Surgical Building daily except Sunday, from nine to one. 4. Daily surgical ward visits at which visiting physicians will be welcome. 5. Clinic in medicine and pathology Tuesday at twelve, by Drs. R. C. and H. Cabot and O. Richardson. 6. Medical clinic Thursday at twelve, by Dr. D. L. Edsall.

PETER BENT BRIGHAM HOSPITAL.—Physicians visiting the city will always be cordially welcomed at the Peter Bent Brigham Hospital.

The medical visit takes place regularly every morning beginning at 10 o'clock.

Operations are usually going on throughout the forenoon in the surgical amphitheatre.

The surgical clinic is held in the clinical amphitheatre on Wednesdays at 12.30 p.m.

The medical clinic is held in the clinical amphitheatre on Mondays at 12.30 p.m.

The clinico-pathological demonstration is held in the clinical amphitheatre on Fridays at 3.30 p.m.

BOSTON MILK AND BABY HYGIENE ASSOCIATION.—For the week beginning January 18, there has been booked at B. P. Keith's Theatre a one-act play entitled "Milk," by Miss Una Clayton, which aims in a very popular way to teach the lesson of the importance of

pure milk with special reference to infants and baby hygiene.

On Tuesday morning, January 19, at 11 o'clock, a public meeting will be held at Keith's Theatre at which Miss Clayton will explain her purpose in writing and presenting this play. At the same meeting there will be shown moving pictures dealing with the production of clean milk and welfare work for babies in large cities. This meeting will be held under the auspices of the Milk and Baby Hygiene Association of Boston. Admission will be free.

SOCIETY NOTICE.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, January 29, 1915, at 8.15 p.m.

The following papers will be read:

1. "Acidosis in Children," Arthur A. Howard, M.D., Boston.

2. "Parenteral Immunization in Conditions of Proteid Sensitization," J. L. Goodale, M.D., Boston.

3. "Weaning—Its Relation to Anaphylaxis as Shown by Differential Blood Counts," H. C. Berger, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*

R. M. SMITH, M.D., *Sec'y.*

RECENT DEATHS.

DR. HENRY DUSENBURY of Williamsburg, N. Y., died recently in that city. He was born at Albany in 1833 and received the degree of M.D. in 1866 from the New York College of Physicians and Surgeons. He was at one time a United States Army Surgeon. He is survived by his widow and two sons.

DR. KLAUS HANSEN, who has died recently at Bergen, Norway, was born in 1843. He was chief physician of the Municipal Hospital at Bergen and a Fellow of the Norwegian Academy of Medicine and was a leader in the national movement for the eradication of tuberculosis.

DR. JAMES STOPP SHAW, who died at Beachmont, Mass., on January 1, was born at Newcastle, England, in 1838. Migrating to the United States in 1852, he studied dentistry and settled in practise successively at St. Johnsbury, Vt., Sheffield, Iowa, and Fremont, Neb. Returning to Boston, he undertook the study of medicine and received the degree of M.D. from Boston University in 1876. He was a member of the Massachusetts Homeopathic Medical Society, the Boston Homeopathic Medical Society and an assistant in gynecology at the Boston University Medical School. He is survived by his widow.

DR. ALBERT VAN GEELUCHTEN, Professor of Neurology at the University of Louvain, died on December 9, at Cambridge, England.

APPOINTMENT.

Dr. E. O. Crossman of Lisbon, N. H., has been appointed Superintendent of the New Hampshire State Hospital.

MEMORIAL ADDRESSES.*

I.

FRANCIS BISHOP HARRINGTON, M.D.

By HERMAN F. VICKERY, M.D., BOSTON.

FRANCIS BISHOP HARRINGTON was of old New England stock, being descended in a direct line from Robert Harrington, who was one of the selectmen of Watertown, Massachusetts, for fifteen years, beginning in 1679. Robert's grandson received the degree of A.B. at Harvard in 1728. Four generations later came the subject of our sketch. He was born in Salem, August 15, 1854. Within six years his father died, at the early age of thirty-three, leaving three sons to be reared by his widow. In this she received substantial aid from her husband's brother, but the little household had frugal ways. In wartime the children were not allowed both molasses and butter on their bread. The mother was a remarkable woman, with the highest sense of truth, honor, and justice, wise and absolutely unselfish. The children of such a mother were fortunate and it was natural that she received to the end the greatest love and veneration. Their home was on the outskirts of the town, purposely so located by the invalid father, and Dr. Harrington never forgot the happy existence he led as a boy, summer and winter, except for the interruption of school hours, in the open fields and rocky caves of Salem. We can see then that various favorable influences acted on young Harrington: his ancestry, a love and opportunity for outdoor sports, the good schools of Salem,

the modest worldly circumstances desiderated by Solomon, and above all, a perfect mother.

He entered Tufts College in 1873 and was duly graduated A.B. in 1877, standing as to scholarship about seventh in a class of seven-teen. "He quickly won the respect and confidence of his teachers and of the whole student-body." In athletic pursuits he showed general excellence and in the newly-introduced game of football, in which he had had no special training, he was preëminent. A classmate, Professor William M. Hooper, says: "In the great victory won by Tufts [over Harvard] on Jarvis Field, in the autumn of 1875, he was not only unquestionably the best player on our eleven, but proved to be practically invincible to the attacks of our opponents. With the ball safely tucked under his left arm and his long right arm swinging in front like the boom of a derrick, he would tear down the field to a touchdown, leaving in his path a line of Harvard men on their backs." During his college career, he made as has been said, a favorable impression upon the faculty, and in later years he was more than once consulted by the authorities as to matters of college policy.

On leaving Tufts he entered the Harvard Medical School, living for the first year in the College Yard with his cousin, the late Dr. Charles Harrington. During 1880-1881 he served as surgical house pupil in the Massachusetts General Hospital, and in 1882 he received the degree of M.D. He played football on the varsity eleven the first year he was in the Medical School but his whole heart was not in the game. His profession had inspired a deeper and worthier love. Still throughout his life he enjoyed greatly outdoor recreations: tennis, golf, skating, tobogganing, camping, and fishing for trout and salmon in the Adirondaeks and New Brunswick. Often he joined in games with his children, as young

* Read at the meeting of the Boston Society for Medical Improvement on November 23, 1914.

in his spirits as they. Those who were matched against him in any game did not find it wise to think he was beaten till it was entirely over. He did not particularly enjoy sailing but he visited Europe and Bermuda and the Panama Canal. His excursions showed his wonderful recuperative powers and gave a literal meaning to the word "recreation". For example when he started for Bermuda last spring, he had high blood-pressure, and was worn down with work and agonizing abdominal pain, yet in a few days he was so comfortable and joyous and active that it was not easy to believe that his previous symptoms could have had an organic cause.

Throughout his life he read constantly, keeping well abreast of all professional advance and also of the world's progress in general. He had good musical ability. He had a keen sense of humor and caught the diamond flash of a joke wherever it might be; but for him to enjoy it, fun had to be clean and kindly. He faced the truth fearlessly but also he was brave and hopeful and did not forget that the prophecy of a physician may carry with it its own fulfilment. He did not think it wise that the patient should bear the burden of all the untoward possibilities of his condition and he was willing in a critical case to throw his own reputation into the balance if that might help to incline it in the right direction.

In 1882, he began the general practise of medicine in Boston; and in October of the same year he married Miss Abbie Josephine Ruggles of Fitchburg. Of this marriage I cannot omit to say that throughout his life it brought him happiness and inspiration. In 1884, he was appointed physician to out-patients in the Massachusetts General Hospital. Two years later, at the request of others and in accordance with his own preference he was transferred to the surgical side. His subsequent promotions, appointments, and honors have been enumerated in the BOSTON MEDICAL AND SURGICAL JOURNAL of July 16, and in the *Harvard Graduates' Magazine* of September, 1914. They need not be rehearsed now. Our purpose is to discourse, like the storm-tossed Trojans, about our departed comrade. "*Amissos longo socios sermone requirunt.*" What sort of a man is it whose loss we mourn, or rather for whose example and companionship these many years we rejoice? He was big and strong, singularly well proportioned, and handsome. His blue eyes were keen but friendly. His countenance revealed strength, intelligence and refinement. His smile gave warmth and cheer. He had modesty, dignity, common-sense and unusual sagacity. He was high-spirited but he kept his temper. Under provocation, his voice became lower and gentler. He did an immense amount of work faithfully. He was efficient in emergencies but he did not wait for the rare occurrence of unusual needs, to serve others. The little duties and the little kindnesses were constantly and most graciously performed. One inferred his religion from his life.

He was a first-rate physician as well as surgeon, and he would have been eminent in his profession if he had never operated. The time came however, about fifteen years ago, when it was physically impossible for him to continue in general practise, so that he occupied himself with surgery exclusively, with brilliant success. His methods have been discussed elsewhere from a technical standpoint. What impressed the ordinary professional observer was his good judgment and thoroughness and the usually successful outcome. And, as was said of him at the meeting of The Massachusetts Medical Society on the day of his funeral, every patient became a friend.

His classmate, Prof. Hooper, describes him well, in the words of President Eliot: "A man of quick perceptions, broad sympathies, and wide affinities; responsive but independent; self-reliant but deferential; loving truth and candor, but also moderation and proportion; courageous but gentle; not finished but perfecting."

The world is better because he lived.

II.

THOMAS MORGAN ROTCH, M.D.

BY CHARLES HUNTER DUNN, M.D., BOSTON.

THE death of Dr. Rotch on March 9, 1914, was a great shock to all of us whose close association with him had made us particularly interested in seeing his plans attain their full completion. His death marked the passing of one of that group of men who played conspicuous parts in the modern revolution of the practice of medicine. The pioneer workers in Pediatrics were but a small group of men, and among these, both as a teacher and a writer, Dr. Rotch had a wide influence upon his profession.

Dr. Rotch was born in Philadelphia on December 9, 1849; received his academic degree at Harvard in 1870, and his medical degree from the same institution in 1874, and served a term as house pupil at the Massachusetts General Hospital in the autumn of 1873. In 1874 he married Helen Rotch, the daughter of William J. Rotch and Emily Morgan of New Bedford. They had one son, Thomas Morgan Rotch, Jr., who was born on May 21, 1878.

At that period no young man's medical education was supposed to be complete without study in Europe, and Dr. Rotch spent two years studying in Germany, Paris and London. When he returned, there was no one in Boston whose practice was devoted exclusively to the diseases of early life. Disease in infancy and in childhood was not regarded as presenting differences from disease in adult life of sufficient importance to call for special knowledge. Dr. Rotch began his career as a general practitioner, but was soon attracted by the interest of the problems encountered in the struggle with disease as

manifested in early life. The earlier days of his work were marked by his earnest endeavors to separate his chosen specialty from the domain of the general practitioner, and to point out to his professional brethren the need of special knowledge in this field. His field of work was one in which a high death-rate had come to be taken for granted. Gradually, as time progressed and medical practice became more defined, pediatrics came to be recognized as a specialty, and Dr. Rotch was able to concentrate his energies on his chosen problems.

There was at this time little special teaching in pediatrics in the Harvard Medical School. In 1888 the University established a Professorship for the Diseases of Children especially for Dr. Rotch, his title being later changed to Professor of Pediatrics.

I shall assume that the work of Dr. Rotch as a teacher, writer, and organizer is sufficiently known to this audience to require but brief mention here. Among all his activities, I think he will always be known by his contributions to the subject of infant feeding. When he began to study and write upon this subject, our knowledge and practice were in a most chaotic state, and to him must be given the credit for the earliest exact work on feeding which was done in this country. He was the originator of the Percentage Method of Feeding, which, while at first opposed by some, has finally come to be accepted by practically all pediatricists. I believe it is not an over-statement to say that he was the founder of modern scientific infant feeding.

The two great interests of Dr. Rotch's life were the development and organization of the pediatric department of the medical school, and the development and completion of the Infants' Hospital. He displayed marked ability as an organizer; and those of us whom he drew around him could not but catch his enthusiasm. We never ceased to wonder at his energy, and his capacity for the regulation of the smallest details. It was difficult to help him in his work, for he wanted to do everything and attend to everything himself. He never laid aside these interests, even in his last illness, and indeed died in harness. During the last days of his life, it was in vain we tried to persuade him to leave the management of things to others. Every day I had to give him a full account of "how everything was going," and it was difficult to persuade him that anything had been attended to without him. Only a few days before his death, at a time when we believed that at last he had resigned the management of the matters which interested him, and when any effort of mind or body seemed impossible, he insisted on telephoning from his bed to Dr. Morse about some small matter of departmental routine.

Dr. Rotch, early in his career, became convinced that the treatment of disease in early life was so distinct from that of disease in adults, that it could best be carried out in a hospital devoted exclusively to children. Later he found

a marked difference in the hospital requirements of young infants and those of older children. The problem of nutrition in infancy was found to be of such great importance, that the nursing requirements for the carrying out of treatment are entirely different at that age, and that the conditions which a hospital for infants must meet are entirely different from those which prevail in a children's hospital. This led to the establishment of the Infants' Hospital, in its modest quarters on Blossom Street. It was the first hospital in this country to admit patients restricted to the first two years of life. Only those who have worked at the old Infants' Hospital can realize the enormous life-saving work which was carried out there under very inadequate conditions.

In 1902, Dr. Rotch's life was saddened by the death of his only son, who had just graduated from the University, and begun a business career. Tom Rotch, as the boy was known to his friends, had not been strong as a baby, and had indeed presented one of those very problems in which Dr. Rotch later took so strong an interest. I know that it was the study of his early life that first led Dr. Rotch's interest into the field in which he later attained so great a reputation. While Dr. Rotch never recovered from the blow of his boy's death, his finest qualities were never better shown than by the way in which he bore this bereavement. He surrounded himself with the college friends of his son, and threw himself with all the more energy into his professional work.

Dr. Rotch had many friends, and was greatly beloved by his patients. In the outburst of sympathy for him in his loss, a fund was given by his friends for the erection of a new infants' hospital as a memorial to his son. This movement has just ended in the completion of the new building near the Medical School.

Dr. Rotch had much to do with the development and administration of the Children's Hospital, but during the last years of his life it was in the new Infants' Hospital that his interests were centered. His plans were always far-reaching, he looked far ahead into the future. He possessed the imagination which could foresee the results of their fulfilment. I believe he was one of the first, if not the first, to foresee the group of buildings now surrounding the Medical School. He talked to me of this idea long before I ever heard it mentioned anywhere else. The one dream of his life was to see the new Infants' Hospital completed and opened, and to deliver the first lecture in its lecture room. After this his plan was to retire from all his other professional activities, and to devote the rest of his life to literary work, and to the management of the new hospital. It was in the director's room of the new building that he intended to pass his remaining years.

It is rather tragic that his hopes failed of fulfilment at the last moment. During his last years he overworked continually. The severe

strain imposed by the hopeless illness of his wife for four years was more than even his strong constitution could bear. He felt his strength failing, but did not say a word of this to anyone. To our anxious inquiries he always replied that he was feeling better. He concentrated all his energies on finishing his work, on seeing the new hospital completed, and on perfecting the organizing of his teaching department. The first acute breakdown occurred early in February, but he was soon up, and no one could restrain him from going to work again. His final illness began on February 24th, and a collapse on February 28th showed his condition to be hopeless. The new hospital received its first patient on March 3d, six days before his death. Although he failed to see the hospital open, I believe he was very happy at the last, for the building was so nearly completed that he had begun to realize the satisfaction of seeing his hopes fulfilled.

III.

CHARLES PICKERING PUTNAM, M.D.

BY WILLIAM BRADFORD ROBBINS, M.D., BOSTON,

DR. CHARLES PICKERING PUTNAM has taken a prominent part in medicine in Boston in the past forty years. During this time we all have come in contact with him in some way or other. We remember him for some particular trait or act or deed. He will be generally known for the great work which he did, in what might be called *social* medicine. His life work may be said to have been to uplift the human race, to make his fellowbeings happier and better in mind and body. He laid down his life for his friends, and his friends were *us* all.

He believed that the greatest good could be accomplished by organization, and therefore we find him a leader in many societies, which have to deal with social and moral uplift. He was one of the founders of the Boston Society for the Relief of Destitute Mothers and Infants, and was its president from 1904 until his death. Since 1875 he had been connected with the Massachusetts Infant Asylum as physician, and for twelve years was president of the board of trustees of that institution. He was one of the earliest to become interested in the Associated Charities, and it was largely through his efforts that the society is now able to accomplish so much.

He was very active in the reorganization of the Boston pauper institutions. To quote from Mr. Joseph Lee's article:

"From 1892 to 1897 Dr. Putnam took a leading part in the very important movement for the reorganization of the Boston institutions for the care of prisoners, of the poor, and of poor, neglected and delinquent children, being on the

special committee appointed by Mayor Matthews in 1892, chairman of the board of visitors of 1893-94, chairman of the standing committee on pauper institutions of the advisory board appointed by Mayor Quincy in 1896, a steady fighter for the reorganization bill of 1897. When the new system of separate unpaid boards of trustees was established he was appointed a member of the board of children's institutions, and was its chairman from 1902 to 1911, performing in that capacity a great and harassing though invisible and unappreciated, service to his fellow-citizens.

"Dr. Putnam was among the earliest supporters of Dr. James R. Chadwick in founding the Boston Medical Library, of which he was an original member in 1875, an incorporator in 1877, and which he served upon important committees until his death. He helped to organize and carry on the Directory of Nurses. He was active in the campaign against tuberculosis and a director of the Mental Hygiene Association. He was one of the first to take up broad social questions from the legislative end, was the first experienced charity worker to enlist in the Massachusetts Civic League, and helped secure the establishment of the State Board of Insanity, the taking over of the Boston Insane Hospital by the state, medical inspection in the public schools of Massachusetts, playgrounds, better probation service, the juvenile court, better laws dealing with tramps, with drunkards, and many others."

Besides all these societies he was affiliated with many medical societies. He was president of the American Pediatric Society in 1898.

During all these years he attended assiduously to a large practise. He seemed never to tire, and no matter what time of the day or night he was called, he had always the same quiet thoughtful, calm, self-contained manner. No matter how busy he was, he seemed to have unlimited time to spend on the details of kindness, the little kindnesses which most leave undone or despise. He never appeared to be in a hurry, and left the impression that this visit was the only one he had to make. He seemed to know by instinct what would comfort most. I have seen him sit down on the floor of the nursery and work over some complicated toy for an hour at a time, so that in the morning when the sick child awoke he would find his toy all fixed and ready to be played with.

How much he loved the children was shown by the way the children loved him.

He had a great faith in therapeutics and his choice of drugs was adapted to suit the individual case with rare skill. He respected the idiosyncrasies of his patients, about drugs or other forms of treatment, but he was very firm when he knew that a certain course of treatment was essential. He was constantly studying to increase his knowledge of new drugs or new combinations of old drugs, which might give better results, or the same results in a less obnoxious manner.

His prescription books are filled with prescriptions which show his mastery of therapeutics.

With his keen sense of humor and kind heart he frequently accomplished what no medicine would do. When the case required some mechanical assistance, he was never at a loss. With the most crude home-made materials he would construct a complex apparatus. He was a born mechanic, and loved to work in his workshop over some useful article, seldom for himself. His office contained many simple and complicated devices to relieve pain and correct deformities. When in his last illness it caused him pain to lie down, he had a wonderful apparatus rigged up under his direction to support himself, an apparatus which he had devised to help one of his friends in a like predicament. I think that if he had had more time for the training and his eyesight had been better, he would have taken up surgery, he was so skilful with his hands.

One of the most striking of Dr. Putnam's traits was his pertinacity. No matter how difficult or apparently impossible the task seemed, he would never give up or be discouraged. I shall never forget the care and patience with which he worked over the case of a young mother who was bent on nursing her child. With an earlier baby the nursing had been intercepted by a breast abscess, and it appeared as if it were impossible to prevent the same thing happening again. The mother was disconsolate. He said that he believed that it was safe to go on nursing. He tried breast bandages, shields of all kinds, made an improved breast pump, and finally succeeded in quieting the inflammation and the nursing went on.

His resources seemed endless either for a broken toy or a broken heart.

Not content with giving so much time to the poor and the needy through his societies, he took the problems of all who came to him as his own. Rich or poor, their problems were his. He believed in organized charity but he gave his life to his own personal charity. The friend to the friendless and helpless, his office was filled with those who needed help or advice, for they knew that they would get an honest opinion, a kind word, a true friend, a helping hand if they came to him.

During his last illness I saw some of the cases that came to his office looking for their friend. I found a young girl whom he had talked to daily, for weeks, to encourage her in the work that she was doing; an old woman whose pills had given out, who said she came for more pills, but who really came to see him; young girls from his societies, who had practically no other friend in the world; and the tired mother of some six or eight children, who came to ask advice about her family troubles. He had seen them all for love.

He was young in his heart, and in his mind, and in his body. He often joked with me because I called a person old. "Why," he said

"they're not much older than I am, and I'm not old!"

He was by inheritance a gentleman and a gentle-man, in the truest sense of the word, he lived. What his forbears have done for Boston is well known.

All that he did we cannot yet fully realize. Descended from great physicians on both sides of his family, he inherited a love of medicine, and a wonderfully keen medical sense, and he also inherited from them a love of service to the people.

Dr. Putnam will be known for his great work for social progress and social medicine, but we shall remember him for his persistent self-sacrifice in his daily work.

Thoughtful of his patients to the last, it was with difficulty that we could get him to discontinue the use of two telephones in his sick room. He knew that he could not get better, but there were few if any, who guessed it, when they heard his cheering words to them.

His last thought was for those he loved—his fellowmen.

COMPENSATORY EXERCISES AS AN AID IN THE TREATMENT OF LOCOMOTOR ATAXIA.

BY H. M. SWIFT, M.D., PORTLAND, ME.

IN considering the treatment of locomotor ataxia it should be remembered that we are dealing with a clinical condition resulting chiefly from a degenerative lesion of the nervous system. The seat of this degeneration is in the fibres of the posterior nerve roots and their prolongations into the spinal cord, the regions of the cord which are affected most strikingly being the posterior columns, perhaps more familiarly known as the columns of Goll and Burdach.

The principal function of the nerve fibres which pass upward in the posterior columns is the transmission of impulses which convey the sense of position to the brain and lower centres. So, if, for example, the fibres in the posterior columns which transmit these sensory impulses from the legs are destroyed, the patient is unable with closed eyes to know accurately the position in which the limb or segment of limb is placed if held flexed or extended at any of the joints.

The loss of position sense in ataxic cases may be often easily demonstrated by bending the great toe up or down and asking the patient to tell with closed eyes the position in which it is held. Usually if much ataxia is present this cannot be done correctly, although in the early

stages before much ataxia has developed the test may be negative.

Inasmuch as in locomotor ataxia the motor pathways are generally intact, there may be no actual loss of power, and strictly voluntary movements can be carried out. It must be understood, however, that no exact movement is entirely voluntary or consists merely in the contraction of one set of muscles, but that exactness is made possible only through the regulatory or inhibitory influences of co-working or opposing muscles whereby the muscles concerned are made to work in harmony and the component movement rendered steady.

This regulatory action is largely involuntary and is made possible by the fact that afferent impulses or messages are being continually sent in from the joints to the central nervous system, which inform the spinal regulatory or coördinating centres of the exact position of the limb during the various periods of time covered by any of its movements, while the centre in turn sends back regulatory motor impulses to the different sets of muscles involved so that the total result is a coördinated movement. But if now, as in locomotor ataxia, the pathways for position sense are destroyed, then the production of regulatory impulses is prevented or at least impaired, and the result is unsteadiness or overaction of muscular movement—in other words, incoördination.

To illustrate what is meant by the regulatory influence of associated movements let us consider the act of standing.

In normal standing the knees are not held ordinarily in a position of stiff and complete extension, but rather slightly flexed so that unless prevented there would be a tendency for them to sink down and give way under the body weight. Normally this giving way is prevented by the fact that whenever the knees tend to bend under the body weight, unconscious sensory impulses are sent in to the coördinating centres of the cord, indicating that a faulty position is being assumed, and are there converted into motor regulatory impulses, which in turn cause appropriate opposing contractions of the quadriceps. In this way the exact amount of extension requisite to normal standing is maintained. But when, as in advanced tabes, this regulatory function is interfered with and the tendency to sink down under the body weight is unopposed, the standing position is not so easily maintained and the patient must resort usually to rigid hyper-extension at the knees in order to prevent them from giving way.

Again, in walking the same principle is involved. Walking is made up of a number of nicely adjusted component movements. In describing this act the legs may be designated conveniently as the supporting leg and the swinging leg. At the beginning of a step one leg is swung forward, while the body weight is supported by the other leg; but soon after the

swinging movement is begun the body weight is transferred from the supporting leg to the swinging leg, the transference being complete as soon as the swinging leg is firmly fixed upon the floor.

This transference of the body weight from one leg to the other is brought about by the plantar flexion of the foot of the supporting leg (now remaining in the rear) which rising in this manner throws forward the body weight upon the leg in front. The latter in its turn now becomes the supporting leg. The other leg in the rear is then ready for the forward swing which goes to make the next step.

In order that the act of walking be properly performed these various movements must be executed with perfect steadiness and accuracy. For example, when the weight is thrown forward from one leg to the other, it is necessary that the foot be raised exactly to the proper position and no further, because if the heel is raised too high the body weight is brought forward so far that the person loses his balance and tends to fall over. Normally this exaggerated movement is prevented because through the afferent nervous impulses one is made aware unconsciously of the exact position of the ankle joint during each instant of the act, and when the plantar flexion has been sufficiently carried out a message to that effect is sent to the cord along the fibres of position sense, which is there transformed into motor impulses to the opposing muscles (peroneals, tibialis anticus, and extensor longus digitorum). In this way the movement is kept within proper bounds. When, as in locomotor ataxia, this sensory pathway is destroyed, such a message cannot be sent to the muscles which normally would inhibit too great a plantar flexion, and when this movement is attempted the result is an exaggerated flexion with accompanying difficulties of locomotion, instead of a regulated flexion, as in normal walking. In locomotor ataxia the ability to transfer properly the body weight from one leg to the other is often lost and is particularly difficult to re-acquire.

Ataxia is thus seen to be dependent upon degenerative changes in the nerve tissue whereby the position sense is destroyed or impaired. It is probable, however, that associated with these degenerative changes is sometimes a more active irritative or inflammatory process in the spinal meninges, which gives rise to the pains and various crises by causing a constriction about the posterior roots as they pass through the pia enveloping the cord.

While it can hardly be definitely proven that the pains and crises are caused by irritation of the posterior roots by an acute process, therapeutic evidence of this is suggested by the fact that particularly in those cases with predominating pains the administration of salvarsan is most likely to prove of value. It is now considered proper by many to give salvarsan in all

cases of tabes, and there would seem to be no doubt that a certain proportion of these cases are improved and in others the process at least checked. But we cannot hope that salvarsan or any other medicinal agent will bring about the restoration of nerve tissue, which has actually undergone degeneration, any more than we can expect that a kidney which is the seat of a chronic nephritis can be made normal again.*

Now let us suppose a case in which salvarsan has been given, the acute process checked with relief of pains, but in which a considerable degree of ataxia still remains. Can anything more be done? It seems to me that the situation here is not unlike that in the case of the degenerated kidney; for in the latter condition we try to bring about compensation by making the skin and bowels take up a part of the work of elimination, and on somewhat the same principle in locomotor ataxia we may utilize the intact sensory fibres of other regions of the cord to take up the work which normally belongs to the posterior columns. Here, however, the analogy between the degenerated nerve tracts and the degenerated kidney ends, inasmuch as in the case of the diseased kidney we have in the skin and bowels compensatory agents ready at hand, while in the tabetic the compensatory function must be developed slowly by a process of re-education.

The method employed to bring about this improvement in function consists in the use of compensatory exercise treatment devised by Frankel, of Heiden, in 1882, and later modified by Foerster, of Breslau, the aim of which is to overcome the ataxia by training the eye and equilibrium sense to compensate for the lost position sense, and eventually to redevelop the position sense itself by increasing the capacity of the fibres in the posterior columns which have escaped degeneration.

In the original Frankel exercises more or less apparatus is used and the patient practices various movements requiring great exactitude in execution, such as putting the feet into small depressions in a board or touching in succession with the feet swinging wooden balls, the idea being that the coördinating ability acquired in this way will increase the efficiency of the whole motor system, including of course the acts of standing, walking, etc. It has been found, however, that improvement in standing and walking is not particularly hastened by these complicated exercises, but that the tabetic learns walking best by practicing walking, the standing by practicing standing. The employment of those other refinements is thus unnecessary.

In the Foerster modifications these more elaborate measures are omitted, and, instead, the motor disturbances seen in walking, standing, etc., are analyzed into their component parts

and the patient taught to correct each of these elemental inaccuracies by a process of voluntary attention.

I shall now attempt to describe some of the details of treatment.

WALKING.

By way of preliminary I would say that my analysis of the tabetic gait is not intended to be complete and that I have chosen merely four important abnormalities in order to illustrate the methods used for correcting them. These abnormalities are:—

1. *Hyperextension at knees.*
2. *Overaction of swinging leg with exaggerated dorsal flexion of foot.*
3. *Lack of plantar flexion of foot of supporting leg to throw the body weight forward.*
4. *Faulty position of hips with corresponding faulty posture of trunk.*

These defects vary considerably in different cases.

Hyperextension at knees. In normal walking and standing the legs are held in a position of slight flexion at the knees. In this position there is naturally a tendency to sink down under the body weight which is corrected by means of unconscious sensory impulses, which are transformed into reflex motor impulses and cause appropriate contractions of the quadriceps muscles, thereby maintaining the necessary opposing extension. In this way, by the unconscious interplay between the actions of the quadriceps and hamstring groups the exact amount of bending at the knees is maintained which is requisite to the normal walk. In tabes, on the other hand, owing to this lack of finer adjustment by means of the position sense, the tendency for the legs to give way can be prevented only by keeping them in a state of stiff and complete extension. In other words, the patient walks stiff-legged, using his legs somewhat as a pair of pegs after the manner of an automaton.

This adjustment is to a certain extent conservative, and it may be inadvisable to try to correct it during the earlier stages of treatment. Later the patient may practice slowly the movement of sinking and rising at the knees, always watching himself carefully and exerting himself most strenuously to avoid all jerks. This exercise is usually very fatiguing and at first it may be necessary partially to support the patient. Standing also may be practiced with the knees in a partially flexed position.

Further measures tending to correct this defect are included under other exercises mentioned later.

Overaction of the swinging leg with dorsal flexion of foot. Owing to the lack of inhibition on the part of the opposing muscles, the leg is swung forward with a jerk. The foot is held stiffly in a position of dorsal flexion and the heel strikes the floor with a thump.

* The Wassermann reaction and the examination of the spinal fluid are valuable aids in judging as to the probable efficiency of salvarsan treatment. For details as to this see papers by Spooner and Ayer, *Boston Med. and Surg. Jour.*, Vol. clxx, No. 13.

Also, "Serology of Nervous and Mental Diseases," Kaplan.

To correct these defects the patient practises walking with the leg sharply flexed at the knee and with the foot pointing downward in exaggerated plantar flexion, thus touching the floor first with the toe and then coming down gradually on the whole foot. The proper motion in this exercise resembles that of the fore legs of a horse drawing a load up hill. The exercise is to be practiced slowly, aiming at perfect steadiness and carefully trying to avoid jerkiness. At the beginning of the movement the foot often leaves the floor with a little twist and this tendency should be perseveringly combated. In the majority of cases the foot is usually best held pointing directly forward, thereby correcting the frequent tendency toward extreme outward rotation. Whatever position is chosen for the foot it should not be allowed to deviate from that line.

Exactitude may be aided if chalk marks or painted spots are made upon the floor corresponding to the shape of the foot and in the exercises the toe be put down exactly upon the indicated places, the patient always endeavoring to correct with constant and painstaking attention any tendency of the foot to swerve.

Lack of plantar flexion of supporting leg to throw the body weight forward. Normally in the act of taking a step the body weight is thrown forward by the rising up of the rear supporting foot into a position of plantar flexion. In tabes the foot of the supporting leg is not raised but tends rather to be merely pushed along, while the upper part of the body, instead of being thrown forward, inclines to fall backward. This defect is to be overcome by having the patient practice to throw the body weight forward by means of careful attention to the movements of the supporting foot.

In the exercises previously described the defects are corrected by training the eyes to watch the various movements and to correct aberrations of movement as they are seen to occur. In the next defect of which I shall speak compensation is effected not alone by visual means, but also by the training of the equilibrium sense.

Faulty position of hips with corresponding faulty position of whole trunk. In the tabetic the hips tend to protrude on the side of the supporting leg which is the opposite of the normal walk, and the balance is maintained with difficulty when the swinging leg is in the air. There is thus a tendency to fall over toward the side away from the supporting leg, which the patient naturally tries to overcome by walking with a broad base and by turning the feet outward in an extreme degree. The problem here becomes one of training him to walk while keeping the hip held in on the side of the supporting leg, because when this is done the trunk bends over away from the unsupported side and the equilibrium is more easily maintained. The attainment of this correct position may be aided at first by the physician's pushing in against

the trochanters of the patient as he walks. Another defect in advanced cases is the tendency of the trunk to bend over forward, which is to be corrected by keeping the buttocks forward and this again may be aided by pushes or slight taps against the sacral region from behind. By such measures the patient may gradually learn to hold the hips in the proper position.

The tendency to fall in any direction may be in part corrected by developing the equilibrium sense so that it learns to respond more quickly than normally. Have the patient notice his tendency to topple over can be overcome in a measure by quickly pushing out the pelvis along the line in which he feels himself falling. Associated with this movement is a compensatory bending of the upper part of the trunk to the other side so that the balance may also be maintained by simply leaning in the opposite direction. This is, of course, the same principle by which the balance is maintained in the normal individual. Normally this maintenance of equilibrium is involuntary and conditioned by unconscious sensory impulses. In tabes these involuntary nervous processes must be supplemented by balancing motions which are more strictly voluntary and may be made to act as compensatory to the lost position sense.

It may have been noted that in some of the exercises the legs are in a position of over-correction, as when, for example, the swinging leg is held strongly flexed at the knee with the foot pointing sharply downward, thus over-correcting the natural tabetic tendency to walk with legs stiffly extended and with feet turned upward. The aim of this over-correcture is to obtain as a total result an approach to a normal walk in which the position of the limb is midway between the extreme position naturally adopted by the tabetic, and the extreme position of the exercise.

If necessary, the exercises may be practiced by aid of the support of another person; then successively with sticks, without sticks; and finally with closed eyes, the difficulty of the task being increased as fast as the progress of the case permits.

In the foregoing description only some of the more typical abnormalities have been considered the object being rather to illustrate a principle than to give an exhaustive description of all the exercise movements. The physician should always analyze carefully the defects of a given case and apply corrective procedures suited to the individual. With a trifling amount of ingenuity appropriate exercises may be easily devised. Care as to detail is imperative, and during the practice the attention of the patient is to be directed to the slightest inaccuracies.

After a certain amount of improvement in walking has been attained, more difficult co-ordinated acts may be tried, such as going up stairs (the body weight being kept well forward), then running, dancing and the like, the

aim not being to acquire excellence in such accomplishments, but only to render easier the act of walking.

These exercises may be often advantageously combined with some of the original Frankel movements which are especially useful as a preliminary if the patient is bed ridden. In practicing them the patient rests in a half reclining position on a firm couch with the back against a support, so that he may watch all parts of the legs.

A description of the movements may be found in many text books, but for convenience some of them are given below:

Slowly raise and lower whole leg from table carefully avoiding all rotation of foot.

Slide foot back and forth in flexing knee. The heel rests upon the table and the foot is held in a position of plantar flexion.

Same as above until knee is flexed, then the foot is raised from the table and the leg extended. Attention that movement is without jerkiness, that foot remains flexed, and that the leg does not rotate.

Place heel upon knee of other leg, then half way between knee and ankle, upon ankle, upon great toe. Same precautions as above.

Slide heel of one foot up and down upon the tibia of other leg, keeping foot in plantar flexion and avoiding rotation.

All these exercises are to be practiced first with eyes open, then with eyes closed.

For cervical tabes with resulting incoördination of the hands appropriate exercises have also been devised.

STANDING.

In cases with far advanced ataxia standing is impossible, because the patient is unable to maintain extension either at the knees or at the hips. As a consequence of this the knees tend to give way and the trunk collapses over forward so that the person doubles up like a knife. In ordinary cases standing is possible, but rendered so only by rigid over-extension of the joints in question. Thus the trunk is bent over backward with corresponding protuberance of the abdomen, while the knee-joint is held stiffly hyper-extended. This hyper-extension of the knees and hips is in a measure conservative and in severe ataxia the patient may be allowed to retain this position during the early stages of treatment, inasmuch as the acquirement of the ability to stand in any manner whatsoever is a distinct gain and at the beginning this may be accomplished only with the maintenance of rigid over-extension, even this sometimes being impossible without the aid of support on both sides. While thus supported the patient must always be on the alert to combat the tendency to collapse by making voluntary extension of the muscles about the knees and pelvis, to do which it is necessary that he watch attentively the parts and make appropriate corrective movements

whenever he sees himself giving way. Later as he becomes more and more proficient, the support should be gradually diminished and replaced by canes until eventually he becomes able to stand alone.

Where the ataxia is less extreme and the patient already able to stand without support the problem becomes one of tempering the rigidity of the extension by the cultivation of a certain degree of flexion of the opposing muscles. In such cases standing is to be practiced in a normally erect position, which will be somewhere between the backward over-extension of the trunk and the forward collapse. The knees are to be held slightly flexed as in the normal.

As in walking, so in standing, the equilibrium sense must also be developed and the patient learn to prevent himself from falling by pushing out the pelvis in the direction toward which he feels himself swaying. The use of the equilibrium sense is particularly valuable when he comes to practice standing with closed eyes.

After the patient has learned to stand reasonably well without support of any kind the difficulty of the exercise should be increased by having him stand with the feet close together and then on one foot. Finally all the exercises are to be practiced with closed eyes, the aim being to rely less and less upon the visual and more and more upon the equilibrium sense.

At first all exercises are to be practiced for only short periods of time, with frequent intervals of rest, because, as should always be borne in mind, the tabetic may have no subjective feeling of fatigue and in his early enthusiasm easily overdo and carry the work to a point injurious to himself. To prevent this the physician should watch the pulse and if it becomes rapid at any time have the patient rest.

At the beginning of treatment half hour seances, including intervals of rest, are ordinarily long enough. Later the exercise periods may be lengthened. Patients often wish to practice at home and this may be permitted, provided they can be made to understand that the exercises may actually retard progress if carried to the point of fatigue. For home work it is perhaps safest to prescribe periods of five to ten minutes' practice, repeated after long intervals several times during the day. As a matter of fact, home practice does not hasten improvement as much as might be expected. To be most beneficial the exercises should be done under supervision, because slight inaccuracies requiring correction continually arise, which escape the notice of the patient.

To be of marked benefit the treatment must be continued over long periods of time, varying from six months to a year. The method is not suitable for all tabetics, the more common contra-indications being optic atrophy, a heart lesion, poor general physical condition, and frequent pains or crises. Nor can one say absolutely whether the exercises will be helpful in

a given case. The fairest way perhaps is to propose to the prospective patient a few weeks' trial and if at the end of that time he is dissatisfied with his progress he may discontinue, although usually if the treatment is carried out even for this short period he becomes interested and willing to keep on.

In conclusion I would repeat that the compensatory exercise treatment is not suited to all cases of locomotor ataxia, and is to be combined with other measures directed to the improvement of the general health and often with anti-syphilitic medication.

Die analytische Methode der kompensatorischen Uebungsbehandlung bei der Tabes Dorsalis. O. Foerster. Deutsche medizinische Wochenschrift, 1913, Nos. 1, 2 and 3.

DIABETES AND SURGERY.

By EDWARD H. RISLEY, M.D., F.A.C.S., BOSTON,

Assistant Surgeon to Out-Patients, Massachusetts General Hospital.

THIS paper has for its object a brief summary of our present-day knowledge in regard to glycosuria in its relation to surgery.

1. In what type of cases must we avoid surgery in diabetics?

2. What is the probable mortality from operations on diabetics?

3. Is the amount of sugar of prognostic value?

The statement made in most text-books that all but emergency operations should be avoided on diabetics and that there should be a very guarded prognosis, does not seem in the light of present surgical technic to be a warning that needs as serious attention as formerly.

The only way to reach a definite conclusion is to study the results that have been obtained after operations on diabetics and the causes of failure, in order to define the limits of surgical interference.

It is very often difficult or impossible to distinguish between temporary or non-diabetic glycosuria and true diabetes, this being notably so in the presence of surgical complications, and should we take the presence of sugar as an indication of the existence of diabetes in all cases there would be many patients who would die unrelieved of their surgical necessity.

Verneuil in 1884 said, "I hardly admit the separation, no one so far having shown clearly where glycosuria ends and diabetes begins. I have, in light of present-day facts, decided as a surgeon to discard the existence of an arbitrary division which does not present any practical utility. From the surgical point of view the presence of glucose in the urine, whatever its amount, is always a serious fact."

The classification of Smith and Durham (Guy's Hospital Report, Vol. xlix, pp. 343-432) seems to more nearly approach completeness and practicability than others hithertofore given. This (somewhat modified) is as follows: Our cases can be divided and more accurately studied if we class them as:—

1. Those cases in which glycosuria is caused by the surgical lesion.

2. Those cases in which it causes the surgical condition.

3. Those cases in which the two are independent and do not influence each other.

4. Those cases in which glycosuria is a harmful factor and adds to the danger of the already present disease or injury.

We must bear in mind in analyzing these cases that glycosuria may be transitory, i.e. due to the use of drugs such as morphia, or it may be the beginning of a true diabetes, the one passing imperceptibly into the other.

Class 1. Glycosuria is not uncommonly caused by the surgical lesion in cases of injury and sepsis. The amount of sugar is generally small (1 to 2.5%) and usually transitory. In ulcerated new growths the glycosuria is probably secondary to the sepsis present. Smith and Durham (*vide* above) instance several cases in which a gradual disappearance of sugar took place after the removal of a sloughing malignant growth. There are many instance in the literature in which glycosuria cleared up subsequent to operations for appendicitis, pyosalpinx, strangulated hernia, ovarian tumors, traumatic gangrene, etc. In such cases, therefore, surgery is indicated and demanded both in light of results obtained and the nature of the surgical lesion.

It may be argued that it is impossible to tell before operation whether the condition is one of transient glycosuria, dependent on the surgical lesion, or whether it be a true diabetes. This is a proper question to raise. But it has its answer in the surgical necessity of the cases and the low mortality statistics resulting from present-day technic.

Class 2. Phillips (*Lancet*, May 10-17, 1902) has written the most careful recent review of the cases reported in the literature on this subject. He thinks it doubtful whether diabetes can directly cause any lesion requiring surgical treatment except balanoposthitis and cataract. His belief in regard to so-called diabetic gangrene is that it is rather a gangrene occurring in a diabetic subject, the influence of the diabetes being indirect through the coincident arteriosclerosis or nerve degeneration, these being the result of the constitutional affection. Carbuncle, he believes, is to be regarded in the same light.

Should we differ from this opinion, we may regard diabetes as a direct cause of the surgical condition and therefore demanding surgical intervention. Mortality from operation in this class of cases is notably high but has been greatly lowered in recent years by the use of

newer forms of anesthesia, such as nitrous oxide and oxygen, local and spinal anesthesia to replace the more toxic chloroform and ether, rapid aseptic technic and careful pre-operative treatment aimed at the reduction of sugar.

Exact mortality figures in this type of cases are not at present available but it is possible to state that the risk of operation is justifiable provided the general condition of the patient and the diabetes can be first improved by preliminary treatment.

Class 3. This from the point of view of surgical prognosis and treatment is in a way the most important group, as it contains new growths, fractures and other injuries, such as genital injuries following childbirth, occurring in diabetics, and especially because the existence of the diabetes may at the time of the surgical emergency be unknown, as the disease may be intermittent.

Phillips has analyzed the results of operations on the face and mouth for malignancy in the presence of diabetes, and finds out of 16 cases 11 recovered, or 68.75% recoveries and 31.25% mortality. Of purely mouth and lip cases, 9 out of 12, or 75% recoveries.

In operations on the breast, of 15 cases 13, or 86.6%, recovered and 13.4% died. Both fatal cases died as a result of sepsis; one of erysipelas and one of sepsis in the drainage tract. In operations on the female generative organs, out of 24 operations performed on 23 patients there are five deaths, or a percentage of 76.25 patients recovering, and of successful operations 79.16%. In purely plastic operations the mortality was practically nil.

The results reported in operations on the male generative organs are very meagre. Of 6 operations on 5 patients, 3 died, giving an operative mortality of 50%. No special precautions had been taken in two cases against coma and the other was in the removal of a septic sloughing penis. Mortality statistics in this class of cases are probably much better than the figures indicate.

When we consider abdominal operations including hernia, appendicitis, colostomy for malignant disease, we find in 15 operations on 15 patients, 11 recoveries or 73.3%. This is a low percentage of recoveries as three of the cases in this series were practically moribund when operated. Three pancreatic cysts in diabetics have been drained, the patients recovering from the immediate effects of operation, but dying subsequently of diabetes some months later.

In operations on the extremities for aneurysm, neoplasm, crush, fracture, etc., 7 cases showed 3 deaths or 57.1% recoveries, 9 operations being done, gives a percentage of successful operations of 66.6.

The discussion of the question of the non-union of fractures in diabetics is an interesting one. Text-books teach non or delayed union to be expected. Smith and Durham report 5 cases of

non and delayed union in 9 cases, the 4 other cases having perfect union within normal time. Phillips cites numerous cases of perfect union and believes that considerable doubt should be expressed that non-union is more common. Van Norden's (*Pathologie des Stoffwechsels*, Berlin, 1893, s. 416) observation on the decrease of lime salts in diabetics would indicate that it was advisable to administer the carbonate of lime to diabetics suffering fractures.

It seems evident, therefore, that we may generally expect union of fractures in diabetics, especially if we take the precaution to administer lime salts during convalescence.

Class 4. The question of gangrene and the results of amputation for that condition are interesting. It is beginning, at least, to be accepted today that diabetes is rarely the direct cause of gangrene, but rather it is to be considered secondary to arteriosclerosis in diabetics. The term diabetic gangrene is usually applied to gangrene of the lower extremities. A vast amount of literature has been published on this subject and the subject is further complicated by the fact that ordinarily senile gangrene is often accompanied by glycosuria. The best treatise on this subject is by Gussenbauer (*Über die Behandlung der Gangrän der Diabetes Mellitus. Wiener Klinische Wochenschrift*, 1895, Band xlii, s. 487). He advocates diet and general treatment first. The condition of the arteries on both sides should be carefully investigated. If the pulse be distinctly present in the anterior and posterior tibial and in the dorsalis pedis, local removal of the diseased parts will suffice. If, however, the pulse be absent there, but be well marked in the popliteal, amputation below the knee may be performed provided the gangrene has not spread beyond the dorsum of the foot and that the leg is free from phlebitis and lymphangitis. Otherwise, amputation must be done through the thigh. If in doubt, amputation should always be done above the knee. St. Bartholomew's Hospital Reports for 1884-1899 emphasize the importance of observing the above directions of Gussenbauer, for out of 8 cases amputated for gangrene and done below the knee in the absence of dorsalis pulsation 6, or 75%, died.

Albuminuria is a serious complication. In Phillips' series all cases having it died. The presence of acetone or diacetic acid and an increase in the amount of ammonia excreted is of the utmost significance, and if these are found to be irreducible the prognosis is bad.

The old idea was prevalent that diabetes exerts an unfavorable influence on the per primam healing of wounds, but this apart from sepsis, does not necessarily follow. Perhaps it is well to make the guarded statement that with preliminary treatment of the diabetes before operation good results may be expected in the healing of wounds, but bad in untreated cases.

The question of the result of dietary treatment

before operation on prognosis is of utmost importance. In Phillips' large series there were 82.3% of recoveries in treated patients and 63.63% in untreated cases, a difference in favor of careful preliminary treatment of 18.66%. These facts are significant enough to be impressive.

Diabetes and sepsis: Extensive experiments by Bujund, Nicholas, and Karlinski show that sugar diminishes the virulence of microorganisms but increases their pus-producing properties. The factor of sepsis is therefore largely influenced by lowered vitality produced by the circulation of an abnormal amount of sugar, the presence of arteriosclerosis and of nerve degeneration producing trophic changes. Sugar directly lowers the vitality of the tissues and indirectly induces chronic vascular changes, both of which are exceedingly favorable to the development of sepsis.

Sepsis, on the other hand, may produce a temporary glycosuria, but nevertheless, this may later be found to be evidence of a diabetes which was quiescent and lighted up by the disturbance to the system incident to operation.

An interesting phase of this subject and one scarcely ever spoken of except by foreign surgeons, is otitis media and mastoid involvement in diabetes. Kuhn, Raynaud and Wolf consider that there is a special form of diabetes in which mastoid symptoms predominate. Frederick explains this by the fact that the mastoid condition is due to the existence of arteriosclerosis. Of 50 cases collected and reported by these authors, 17 developed acute mastoid disease, 11 developed slight mastoid symptoms and 22 had none at all: a percentage of 56 with mastoid involvement. This condition is not surprising when it is considered how often sepsis thrives in the presence of diabetes. Extensive deep cellulitis of the neck is liable to follow mastoid operation. This should by no means contraindicate operation however.

The following rules may be laid down in regard to operations on diabetics:—

(a) A thorough examination of the urine must be made in every case, especially for the detection of acetone and diacetic acid.

(b) The total amount of ammonia must always be estimated. No operation except of the extremest emergency should be performed if there is one gram of ammonia excreted in 24 hours, until this has been reduced to the normal amount, .75.9 gm.

(c) An operation should be postponed should there be acetone or diacetic acid, even if the amount of ammonia is normal.

(d) Much albumen in the urine is a contraindication to operation and even in small amounts is of bad prognostic import.

From a review of the foregoing data it will be seen that most of the major operations of surgery have been and can be performed with success on diabetics.

In Phillips' extensive series gathered from the literature the percentage of recoveries was 72.28, or a mortality of 27.72%. This, at first glance, seems a large mortality, but when the seriousness of the condition and the poor condition of some of the patients operated on is considered, this is not a high, but a very fair mortality. When such cases as strangulated hernia, extensive malignant disease and sepsis, which in themselves give high mortality, are omitted, we may expect a reasonably low death-rate, and general good results in this class of cases. The percentage of sugar is no criterion, as fatal results have followed from coma when sugar was temporarily absent and cases with large amounts of sugar have often recovered.

The presence of glycosuria should never deter the surgeon from performing any operation of emergency.

Other cases should not be operated in which acetone, diacetic acid and ammonia cannot be reduced by preliminary treatment.

A mortality of 20 to 30% is to be expected in this class of cases.

The use of an anesthetic other than ether and chloroform, careful dietary treatment before operation, the prevention of sepsis and rapid technique will still further reduce the mortality.

THE DIFFERENTIATION OF HUMAN AND COWS' MILK BY COLOR TESTS.

BY RICHARD S. EUSTIS, M.D., BOSTON.

At the suggestion of Dr. Fritz B. Talbot I have investigated several comparatively new reactions for the easy identification of cows' milk and human milk. Two of these depend upon the well-known fact that breast milk is normally less acid than cows' milk. The range of acidity falls within the field covered by the color changes of neutral red, which is an indicator changing from red in acid to yellow in alkaline solution. However, the normal colors of red and yellow are obscured by the white opacity of the milk, so that fresh cows' milk becomes a deep strawberry red and breast milk a duller, brownish or brick red. Furthermore, if ether is added in the proportion of five to one, the cows' milk remains deep red with the supernatant ether slightly red, while the breast milk becomes a pale orange with the ether yellow instead of red.

Moro¹ has described the first part of this test and determined that it is due to the reaction of the milk. For instance, fresh breast milk kept at room temperature gradually becomes acid. Before any change can be detected by smell or taste, the color with neutral red loses its brownish hue and soon becomes a strawberry red, indistinguishable from that due to cows' milk. Also, as Bauer² has stated, it is no longer decol-

orized by shaking with ether. I have found this change to be a gradual one with no definite end point. Bauer gives 38 hours as the limit of time which breast milk can be kept at room temperature before giving the cows' milk reaction." According to my tests the change of color had progressed far enough to be detected in 18-24 hours, and at the same time the milk acquired the power of retaining its color in the presence of ether. If the milk is kept on ice, however, the development of acidity is much slower and the change to the "cows' milk reaction" is correspondingly delayed. I have found a normal "breast milk reaction" in such milk 48 hours after the collection, and undoubtedly if greater care had been taken in the bottling it would have lasted still longer.

Neutral red, although primarily a colorimetric indicator, is also a stain, and if a drop of fresh milk is mixed with it on a slide, then warmed and examined under the microscope, the neutral fat droplets will be found colored yellow. The casein masses which appear as a result of warming, are red. The action of heat is necessary to make the stain penetrate the fat droplets, and even then many of them will remain unstained. As the milk ages the neutral fat gradually changes to fatty acid and stains red. Thus this microscopic method can be used as a check on the test tube method, but is rather too delicate as fresh drawn breast milk will show a few red droplets after it has stood one hour at room temperature. Cows' milk invariably contained some red droplets by the time it reached the laboratory.

A second stain which may be used in much the same way is Nile blue sulphate. This is not a colorimetric indicator like neutral red, but is a blue staining oxazine base, which in aqueous solution is partly oxidized into a red oxazone. The blue base does not stain neutral fat but does unite with fatty acids to form a blue soap. The red oxazone is soluble in all liquid fat, whether neutral or acid, and stains the droplets red. The blue stain of the base, however, is stronger than the red oxazone, so that fatty acids appear blue and neutral fats red. Furthermore, the red oxazone is soluble in ether and can be extracted by it from a watery solution. The oxazine base retains its blue color in the presence of ether only when the reaction is acid. If an alkali is added it turns white, only to regain its color again on the addition of an excess of acid.

Friedenthal³ in 1911 used this stain in aqueous solution to tell whether a suspected milk fat contained pure neutral fat or whether it had partly changed to fatty acid.

Bauer² in 1912 discovered a difference in behavior toward this dye of breast milk and cows' milk. One drop of a 0.25% aqueous solution of Nile blue sulphate colors 2-3 c.c. of breast milk a deep blue, but the same amount of cows' milk a lighter robin's egg blue. The two colors are very distinct and cannot be confused.

This difference in color, however, does not depend on the reaction of the milk, but solely on the percentage of casein. For instance, the green blue color of cows' milk is given equally by skimmed milk, whole milk, and 32% cream. The blue of breast milk appears also regardless of the amount of fat. But 32% cream diluted with water until the fat is 4% and the casein 0.4%, gives a blue color indistinguishable from that due to breast milk. Furthermore, if the milk is curdled by warming, the casein masses are seen under the microscope to stain green. They are much more numerous in the cows' than in breast milk.

The reaction of the milk has nothing to do with the greenish color. Thus, cows' milk made slightly alkaline with soda bicarbonate still turns green with Nile blue, and breast milk made slightly acid with diluted sulphuric acid still turns blue. The behavior of the two milks when shaken with ether is, however, entirely dependent on the reaction, as the following table shows.

	AFTER SHAKING WITH ETHER		
	NILE BLUE.	MILK	ETHER.
Soda bicarb. solution.....	Blue	Colorless	Reddish yellow
Dilute sulphuric acid.....	Blue	Blue	Pink
Fresh cow's milk.....	Greenish blue	Greenish blue	Pink
Fresh cow's milk, soda bicarb.....	Greenish blue	White	Reddish yellow
Fresh breast milk.....	Blue	Bluish white	Reddish yellow
Fresh breast milk, sulphuric acid.....	Blue	Blue	Pink

Inasmuch as the power to decolorize with ether is directly dependent on the alkalinity of the fluid, this test also may be used as a means of judging the age of breast milk. It is of about the same value as the test with neutral red, both showing a change after the milk has been kept about 24 hours at room temperature, or 48-72 hours on ice.

If a drop of fresh milk, either cows' or human, is warmed on a slide with a drop of Nile blue and examined under the microscope, no blue droplets are seen, the great majority are reddish, while a few are unstained. As the milk ages and the neutral fats begin to change to fatty acids, blue droplets appear and increase rapidly in numbers, while others take all sorts of intermediate hues between red and blue. Finally, in sour milk, all the droplets stain blue.

In practice the two tests are used as follows: to 1—2 c.c. of the milk in a test tube is added 1 drop of a 1% solution of neutral red. A reddish brown color denotes fresh, "usable" breast milk, a strawberry red cows' milk or sour breast milk. If the milk is then shaken with five times its volume of ether, a fresh breast milk will decolorize, cows' milk or sour milk will not. A precisely similar test may be carried out with $\frac{1}{4}$ % aqueous solution of Nile blue, except that breast milk colors blue no matter how old, and cows' milk greenish blue. Hence for determining whether a given milk is human or cows' the Nile blue is the better test, and is delicate enough to detect 1 part of cows' milk in 9 parts of breast milk, provided that there is known breast milk present for comparison. For detecting the age or usability of known breast milk there is little choice between the two.

With neutral red there is a change in color, and ether does not decolorize the fluid, after 18°—24° at room temperature, or 48°—72° on ice, depending upon the care with which it has been collected and bottled. Nile blue always remains blue, but loses its ability to decolorize with ether at about the same time. The microscopic test may be used as a check upon the test tube method but is not to be depended on by itself as the chemical change from neutral fat to fatty acid proceeds too irregularly.

There is a third reaction for the separation of human and cows' milk which I have also tested. Engel and Turnau⁴ in 1911 discovered a difference in the behavior of the urine of breast and of bottle-fed infants when it is warmed with a 2% silver nitrate solution. Both urines develop a white precipitate which in the urine of breast fed babies turns brown and then black. This reaction has been investigated by a number of others and is now thought to depend on the excess of chloride in cows' milk over human milk. Hence less chloride is excreted in the urine of breast-fed babies, and consequently after all the chloride available has been changed to silver chloride there is still a surplus of silver nitrate which is then acted upon by unknown

reducing substances in the urine and changed to metallic silver.

Tugendreich⁵ applied this same test directly to the milks and found a distinct difference in their behavior. If equal parts of breast milk and 2% silver nitrate solution are boiled together the mixture will take a rich café au lait color. Cows' milk gives only a dull brownish or sometimes a pale violet. This is probably also a chloride reaction depending for its color change on the action of reducing agents in the milk upon an excess of silver nitrate.

I have confirmed this reaction with a number of different breast milks and have always found their separation from cows' milk easy. Furthermore, I could detect the addition of one part of cows' milk to three parts of breast milk, provided that there was known breast milk at hand for comparison. Dilutions with smaller amounts of cows' milk gave uncertain results. As was to be expected, the age of the milk made no difference in the reaction. Hence, although Tugendreich's reaction is useful as far as it goes, it is not to be compared with either the neutral red or the Nile blue test in the amount of information to be obtained from it.

RECOVERY FROM COCCIDIOIDAL GRANULOMA.

By S. B. WOLBACH, M.D., BOSTON.

IN response to a number of inquiries, by letter and indicated in published reviews of coccidiodal granuloma, the following brief notes are written concerning a case briefly reported by me in a study of the cultures in 1904. (*Journal of Medical Research*, Vol. XIII, No. 1.)

The case was one of coccidiodal granuloma as was proved by the pathological and cultural findings. It is hardly necessary in this day to go into the classification of this disease. Some confusion was introduced by Ricketts, (*Journal of Medical Research*, Vol. VI, No. 3). He brought together under the one heading "Oidiomycosis" a series of cases which we now know to be due to at least three different organisms, namely:—

(1) True blastomycosis or specifically, *Torula* infection. These cases have been extremely rare, and so far as I know none have been reported in man from this continent, with the possible exceptions of the two cases reported by Rust and Farnell (University of California publications in pathology, Vol. II, No. 5, June 21, 1912). Both of these cases terminated in meningitis and were classed as Oidiomycetic by the authors. From the appearance of the organisms, in the sections

sent to me and from the gelatinous character of the lesions due to zoöglia formation described by the authors, I am inclined to believe that these cases were true blastomycosis. In the absence of cultures it is of course impossible to be positive.

(2) Cutaneous and systemic blastomycosis, so-called, in which the organism reproduces in tissues by budding and in cultures has a mould-like growth. Under exceptional instances there may be growth by budding in cultures.

(3) Coccidioidal granuloma in which the organism grows in tissues by endogenous sporulation. On culture media it grows as a mould-like fungus, never by budding.

Blastomycosis, so-called, and coccidioidal granuloma have been reported almost exclusively from America. Over a hundred cases of the former have been reported. In a recent summary by W. J. McNeal and R. M. Taylor, (*Journal of Medical Research*, Vol. XXX, No. 3, 1914) 24 cases of coccidioidal granuloma have been collected. As shown by these authors the name, coccidioidal granuloma, should be preserved for this third type of infection and the name *Coccidioides immitis*, proposed for the organism by Rixford and Gilchrist, (*Johns Hopkins Hospital Reports*, 1896, No. 1) should be preserved, in spite of the fact that the organism was first believed to be a protozoön. It is still necessary to emphasize that Coccidioidal granuloma is a distinct disease and is not to be confused with the cutaneous blastomycosis and the systemic infection sometimes produced by the organism of cutaneous blastomycosis. The summary of McNeal and Taylor is so complete and so recent that nothing can be added to their list. They confirm observations of mine which have an important bearing in the classification of the parasite, namely, that the spheres in tissue develop directly from the "septate mycelial thread," *i. e.* from segments of the mycelium and not from the chlamydospores. They also for the first time succeed in obtaining, in cultures under anaerobic conditions, reproduction by endogenous sporulation.

This case, a woman, was a patient of Dr. William P. Bolles of Boston, who has supplied the following history:

"Previous to 1903 she had travelled a good deal both on and off the beaten track—Europe, India, Japan, etc. In 1901 or 1902 she made her last long trip to California and Mexico. She has had a number of unrelated and minor troubles and for many years, eczema with intense itching, scattered and frequent boils, chronic nasal catarrh (ethmoiditis) and mild but persistent rheumatism, etc. She was operated upon for strangulated hernia in 1899.

"Although she had suffered off and on from boils for some years before, she only spoke of them casually, and my attention was not called to them until 1902 when she applied to me for treatment. There was nothing peculiar about the course of the furuncles except that some did not discharge, and

others, when opened, yielded a thin necrotic material and healed slowly.

"In 1903 two slowly progressive swellings appeared on her head, one on the right side of her forehead at about the line of the hair, the other about an inch above the outer end of the left eyebrow. They were about an inch in diameter, smooth, rather flat and nearly round; at first hard-like periosteal thickening, afterwards they softened in the middle. The one on the right side especially presented a circular edge of bone around the central softening. She declined for several months to have any surgical treatment either for these or for some "boils" under her arm. The cranial nodes were not very tender or painful.

"During the summer of 1903 she was not in my care but had a prolonged x-ray treatment which did not appear to have any effect on the course of the disease. During this time the swelling on the left side of the head burst subcutaneously and its contents filtered downward into the eyelid causing much edema and closing the eye. There were two smaller foci on the scalp, one behind the ear about one-quarter of an inch in diameter.

"In January, 1904, I operated, opening and curetting out all the nodules. They consisted of necrotic tissue with brownish or grayish pus, some granular bodies like miliary tubercles and inflammatory thickening. The mass over the left eye was mostly fluid. Under the two principal swellings, those on the forehead, the bone was entirely disintegrated and the holes about an inch in diameter like trephine openings with smooth perpendicular walls reached to the dura, when the soft mass had been removed with a curette. The dura was not involved. At the same time the nodule under the left arm was curetted and thoroughly cleaned out.

"Recognizing the unusual character of my patient's trouble Dr. Wolbach, at my request, was present at the operation and obtained cultures directly from the lesions and subsequently from rabbits inoculated by Dr. F. B. Mallory to whom tissues were sent for diagnosis.

"Recovery was slow but complete.

"In March she had lobar pneumonia from which she recovered slowly. Specimens of the sputum and urine were sent to Dr. Mallory who was unable to find any organism of coccidioidal granuloma in them. Clinically the case was one of pneumococcus pneumonia. The history of the patient subsequent to operation is as follows: In December, 1911, she had an acute obstructive jaundice. I operated and removed a small calculus from the common duct. The recovery was rapid and uneventful.

"At present she is in a fair condition excepting chronic 'rheumatism'. There has been no return of lesions similar to those which proved to be coccidioidal although there have been a few furuncles which healed spontaneously. In the last few years the eczema has diminished and the furuncles have become less troublesome. She is now about seventy-five years old, is active for her age and attends to her numerous intellectual and charitable interests."

SUMMARY.

This case is one of two cases in the series of 24 recently collected by McNeal and Taylor which have recovered. The other case which recovered was localized in the leg and recovery followed amputation. It is the only case which has occurred in a woman. It is of course im-

possible to prove that the patient does not still harbor the parasite possibly in encapsulated lesions such as occur in tuberculosis. The patient unquestionably showed considerable resistance to the infection as the slow progress of the original lesion indicated. For all practical purposes she is cured, and has remained free from the disease for a period of ten years although subject to ordinary furunculosis.

Clinical Department.

THE ALCOHOLIC INJECTION OF THE INTERNAL BRANCH OF THE SUPERIOR LARYNGEAL NERVE.

By IRVING SOBOTKY, M.D., BOSTON.

Laryngologist, Long Island Hospital and Berkeley Infirmary; Assistant Laryngologist, Mt. Sinai Hospital.

A MORE distressing picture than that presented by an advanced painful tuberculous laryngitis is hard to find. The patients have such exquisite pain in attempting to swallow that they often refuse food. As tuberculous laryngitis is almost invariably secondary to phthisis, a disease where forced feeding is essential, it is easy to recognize that the lessened nutrition materially hastens the outcome.

Pain on swallowing may appear early and is present when any part of the upper aperture of the larynx is involved in the tuberculous process. Involvement of the epiglottis renders the prognosis more dubious and the symptomatic treatment less satisfactory. In such cases the swallowing of solid food causes pain, while in tuberculous affection of the arytenoid region, the swallowing of fluids gives pain.

Ulceration of the posterior wall of the epiglottis or of the arytenoid cartilages produces the most severe pain but infiltration of the muscles or perichondritis can also produce pain.

Various anodynes may be applied to the larynx to render feeding more comfortable. Cocain of 5% strength, novocain, or beta-eucaine may be applied or sprayed on the larynx shortly before meals but orthoform is more advantageous and the effect lasts longer. However, all these anodynes give only fleeting relief and the pain returns in twenty minutes to two hours after application. The blocking of the internal laryngeal nerve by injecting it with alcohol, gives the greatest and most permanent relief to these unfortunate sufferers.

The superior laryngeal nerve is the sensory nerve of the larynx. It is a branch of the pneumogastric and arises from the middle of the inferior ganglion of this nerve. It descends behind the internal carotid artery, between the middle

and the inferior constrictor muscles, and divides into the internal and external laryngeal nerves. The internal nerve penetrates the thyro-hyoid membrane and supplies the mucous membrane of the larynx. The branches of this nerve form plexuses beneath the epithelial layer of the mucous membrane, end in bodies similar to the taste buds of the mouth, and are surrounded by ganglion cells. These are fewest in the vocal cords. The internal laryngeal nerve is accessible for injection at the point where it pierces the thyro-hyoid membrane.

Technic. Place the patient in a recumbent position. Using the usual aseptic precautions, locate by pressure the tender spot where the nerve pierces the thyro-hyoid membrane, usually at the upper edge of the thyroid cartilage and one-third the distance from the outer edge. Introduce a somewhat blunted needle about one and a half cm. into this point at right angles to the skin. Should the patient cough, the needle is in the lumen of the larynx and must be withdrawn. He must be forbidden to talk or to shout and told to signify ear pain by raising his hand. If the introduction of the needle has produced no discomfort, turn it upward and outward toward the ear, and if this does not produce intense pain move the needle cautiously in various directions until the pain, referred to the ear, is produced. The instant the patient shows he is in pain, push the piston of the syringe slowly and allow only one or two drops of the 85% solution of alcohol to escape. If this augments the pain inject one to one and a half c.c.

In successful injections there is little inflammatory reaction about the site. The pain on swallowing disappears and does not return for anywhere from ten days to three months. If both right and left internal laryngeal nerves are to be injected, as is usually necessary, it is best to wait two or three days between injections.

Some laryngologists use a 1½% solution of cocaine with the alcohol, as this mixture diminishes the pain of the injections. However, patients have had so much pain they cheerfully stand the temporary discomfort of injection.

Untoward Results. If the needle is too far back, the superior thyroid or the external carotid artery may be pierced. If too low, the thyroid cartilage; if too high, the hypoglossal nerve. If the alcohol gets into the larynx it produces a local inflammation that adds to the patient's discomfort for a short time. Should the alcoholic injection fail to relieve the pain, it can be repeated in two or three days. It is perhaps needless to say that if the ulcerations are located at parts not supplied by the nerve a good result cannot be hoped for by this treatment. Mettifer reports 17 tuberculous laryngitis cases, with painful deglutition, treated by alcoholic nerve injections. All except one were free from pain within 24 hours. The duration of relief varied from five days to three months. Roth of

Bad Reichenhall, R. Hoffman of Munich and H. Horn of San Francisco report good results.

The author has not had as much success as his colleagues quoted above, but can report encouraging results only. The cases given below were picked at random, as this would seem fairer than to report only the cases where the results have been entirely favorable.

CASE 1. Mr. A., seen at the clinic of Prof. Bruhl, Berlin, June, 1911. Act. 40, diagnosis, advanced pulmonary tuberculosis, tuberculous laryngitis. Was aphonic, complained of exquisite pain when attempting to swallow and had dyspnea. The larynx showed ulceration of the arytenoid region and of both vocal cords. The right internal laryngeal nerve was injected with alcohol; four days later the left nerve was injected. Seen one week after the first injection. Patient said he was much relieved and could swallow food without discomfort. Two weeks later the laryngeal condition was unchanged. Not seen again.

CASE 2. Mr. C. Seen at Long Island Hospital, Boston, May, 1914. Act. 24, diagnosis, advanced pulmonary tuberculosis, tuberculous laryngitis. Examination of the larynx revealed ulceration of the interarytenoid region, edema of both arytenoid cartilages and erosions of the vocal cords. The left internal laryngeal nerve was injected with alcohol. Seen again on June 4. He said he had been very comfortable since the injection and had only slight pain on swallowing. He asked to have the right nerve injected. This was done. The next two days he felt very uncomfortable and complained of pain and burning on the injected side. Two weeks later he said the last treatment had been of no benefit and refused further injections.

CASE 3. Mr. G. Seen at the Mt. Sinai Hospital, Boston, Aug. 1, 1914. Act. 32, diagnosis, advanced pulmonary tuberculosis, tuberculous laryngitis. He gave a history of a throat operation at the North Reading Sanatorium seven weeks before. Examination of the larynx showed the entire mucous membrane pale, with here and there, patches of mucus adherent. The middle portion of the epiglottis was missing, leaving a V-shaped depression. The surface was comparatively clean. Both arytenoids were swollen and infiltrated. The vocal cords were ragged but there was no actual ulceration. He complained of pain on swallowing. The right internal laryngeal nerve was injected with an 85% solution of alcohol. On Aug. 22 he said he had been free from pain for four days following the injection. One c.c. of alcohol was again injected into the right nerve. On Sept. 5 he said he was free from pain for a week following the second injection. At this time his general condition was very poor and the end was apparently near. However in view of the relief afforded him by the previous injections an attempt was made to inject the left nerve. This was not completed because of the weakness of patient. Death occurred two weeks later.

The writer wishes to express his thanks to Dr. Richards of the Long Island Hospital and Dr. Arkin of the Mt. Sinai Hospital for placing the cases at his disposal and for permission to report them.

Medical Progress.

SEVENTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY.*

BY ROBERT B. OSGOOD, M.D., ROBERT SOUTTER, M.D.,
HERMANN BUCHHOLZ, M.D., HARRY C. LOW, M.D.,
MURRAY S. DANFORTH, M.D.,
BOSTON.

(Concluded from page 59.)

CONGENITAL DEFORMITIES.

Congenital Dislocation of the Hip.—Lance³⁵ states that the consensus of opinion in the last decade has favored attempting reduction not earlier than the second year and preferably before the seventh year and not after the ninth. Lance's own opinion, based on cases reduced by himself and others earlier than the second year, is not in conformity with this. He believes that as soon as the diagnosis is made reduction should be attempted.

[Ed. Note.—We have believed that forcible reduction and retention in plaster were best not attempted before the second year for the following reasons: 1. There is less danger of injuring or displacing the epiphysis. 2. Fixative dressings for long periods are not easy to apply or to retain before two years. 3. Manipulation is safer after two years on account of the firmer texture of the bone after some weight-bearing. In the experience of one of the editors in three cases under two years in which simple abduction and traction had been employed, spontaneous reduction had occurred.]

Gangolphe and Plisson³⁶ give detailed histories and radiographic findings in eight cases of what they call latent congenital subluxation of the hip. The symptoms not appearing until the age of 25 to 30 are those of some form of arthritis or coxalgia, and they believe that the Roentgen rays show this latent tendency to dislocation, causing great susceptibility to strain and the development of an irritative arthritis because of the instability. In their hands the avoidance of fatigue and the strengthening of the muscles about the hip joint by special exercises has been sufficient to cause a disappearance of the symptoms.

Congenital Forward Dislocation of the Knee.—Rechmann³⁷ has reviewed fifty-nine reported cases of congenital forward dislocation of the knee and adds two more from the clinic of Prof. Riedinger in Würzburg. There are three stages. 1. Genu recurvatum. 2. Subluxation with lack of power to flex the knee. 3. Forward dislocation of the tibia on the femur. The most striking feature of all the stages is the power of hyperextending the knee, the patients being able frequently to touch the abdominal wall with the toes. The treatment consists in reducing the deformity; in extreme cases lengthening the patellar tendon is necessary. Fixation is fol-

lowed by ambulation in a brace maintaining the corrected position.

Ebert³⁸ calls attention to the necessity of differentiating between cases of congenital dislocation of the shoulder, epiphyseal separations, and the traumatic (obstetrical) dislocations. The characteristic attitude in which the arm lies in congenital dislocation is that of "birth palsy," i.e. adducted across the chest and strongly rotated inward. Upon abduction and outward rotation the slip of reduction is felt, the dislocation recurring as the arm falls. In cases seen early, reposition and fixation in the position of abduction and external rotation is sufficient. Later cases may require quilting of the capsule or osteotomy of the acromion and of the humerus, with outward rotation of the lower fragment.

Free Fascial Transplantation.—Kirschner³⁹ who was the first systematically to use free fascia flaps has written an important and exhaustive paper in which he discusses the results of the use of free fascia in his own and other surgeons' hands. He is still much impressed with the usefulness of the method. Some of its advantages may be summarized: 1. Its availability. Kirschner believes in autoplasmic grafts.

2. Its tendency to heal without reactions even under unfavorable anatomical conditions. 3. Its prolonged and perhaps permanent life in its transplanted position. At length Kirschner discusses the details of its use, the most important being. 1. Repairing tendons. 2. Substitution for articular ligaments and as artificial ligaments to maintain corrected positions of the foot, etc., in poliomyelitis. 3. As restraining bands to prevent dislocations of joints, the patella, or slipping tendons. 4. As interposing flaps in attempts to mobilize stiffened joints. 5. To cover amputation stumps. 6. To reinforce plastics for herniae of abdominal or thoracic walls and to strengthen or replace the dura mater.

[Ed. Note.—There seems to be little doubt that transplantation of free fascia, certainly autoplasmic and possibly homoplastic, will continue to be increasingly employed with success. In our own hands it has proved a most satisfactory material, perfectly tolerated by the tissues into which it has been implanted.]

Giertz⁴⁰, Hofmann⁴¹, and Lewis and Davis⁴² all report successful results with extensive fascial implants in the substitution of tendons and of the plantar fascia of the foot.

JOINT SURGERY.

Arthroplasty.—In earlier reports we have devoted considerable space to the subject of arthroplasty and the reports of successful cases. We believe the subject to be of great importance. It is more possible at present to review end results and to obtain a somewhat more judicial consensus of opinion.

Brocq⁴³ in a long article has reviewed the results of various methods of treatment carried out in different clinics for vicious ankylosis of the knee. He considers that when the angle of flexion is less than 90° resection is usually advisable. He thinks there is no case on record which is above criticism which proves that a permanently useful new joint can be obtained by the method of total graft. He is still sceptical but hopeful concerning the formation of useful joints in the knee by the reshaping of bone ends and the interposition of flaps of tissue or other substances.

Helferich's⁴⁴ review of the subject of arthroplasty, or as he called it before the last International Congress, "Operative neoarthrosis," is also of great value. The description of the technique offers nothing especially new, and the indications for the operation are those laid down by most careful surgeons who have had experience with these procedures. Helferich lays special stress on the wisdom of waiting for a long time after an infectious process has been active before attempting arthroplasty. "One cannot wait too long." He has collected about 300 published cases in many of which the process leading to the ankylosis had not been sufficiently healed to warrant the operation. Of these three hundred, 120 were of the elbow, 75 of the knee, 49 of the hip, 20 of the jaw, and small numbers of most of the other joints. Many of the elbows are satisfactory. The knee operation he considers still in the experimental stage in spite of some individual very encouraging results. Some of the hip cases he considers have been greatly improved and he believes that the shoulder and the isolated ankylosis of the patella offer favorable opportunities. The impression which is left from the review is that a new field has been opened, but that especially in the knee joint, where the greatest need for successful arthroplastic operations exists, there has resulted so far, when the cases are carefully sifted, the least general measure of success.

We have not before reviewed a very careful and helpful piece of research work done by Allison and Brooks⁴⁵. Their quite long series of experiments on dogs was undertaken to determine the tissue changes taking place in joints as a result of the interposition of substances intended to favor mobility. The results which they observed from the use of different substances are most interesting. I. Cargyle's membrane. This persisted only ten days and was of no use in preventing fibrous union. II. Free fascia. Persisted for a long time, but not in a continuous layer. Where parts were destroyed islands of fascia were left, about which the new adhesions between the joint surfaces formed. In two cases in which the fascia entirely disappeared there were no adhesions between the denuded surfaces. III. Pedunculated fascial flaps acted in the same way as free fascia, but the pedicle formed an extra restricting band. IV. Chromicized pigs' bladder (Baer) persisted

longer but caused a marked local reaction and may have been the cause of the considerable adhesions of fibrous tissue that formed and in every instance of its use caused a more or less firmly united joint. V. Fascia impregnated with metallic silver was not in the least irritating, persisted well, and in each case the denuded bone surfaces were covered with a connective tissue layer. Very few adhesions were present and the new bone formation was very slight.

[Ed. Note.—The work of Allison and Brooks is purely experimental on animals and does not attempt to show any functional end results, but it is surely most suggestive and we shall look for later reports of end results of the trial of this method in human cases.]

Fasano⁴⁶ eight years ago replaced a patella destroyed by an old osteomyelitis by a flap of tendon cut from the quadriceps and turned down raw side out and sutured. He reports the end result is still excellent and that similar operations on dogs have given equally good and durable results.

BONE SURGERY.

Certain recent pieces of experimental work concerning the question of osteogenetic function of the periosteum may be grouped together.

Brown (W. S.) and Brown (C. P.)⁴⁷ in a series of 25 experiments on dogs were unable to produce bone from periosteal implants into subcutaneous tissue and muscle. They were unable also to make free bone transplanted into non osseous tissue form new bone. Where a periosteal flap was lifted and carried through muscle back to bone no osseous tissue was produced away from the bone. Transplanted bone in contact with living bone produced new bone. They conclude that periosteum does not produce new bone.

Gallie and Robertson⁴⁸ believe as the results of their careful and seemingly comprehensive experiments that Duhamel, who from his experiments in 1739 concluded that periosteum produced bone, was misled by the growth of the endosteum. They have repeated Duhamel and MacEwen's experiments and are convinced that MacEwen is right and Duhamel is wrong, and that periosteum does not produce osseous tissue.

The results of McWilliams⁴⁹, based on experiments and human transplants, also are in the main like those of other recent observers, though he thinks that periosteum may produce bone in soft tissue. He brings out clearly the value of periosteum as a limiting membrane and a source of blood supply.

Cohn and Mann⁵⁰, repeating most of MacEwen's experiments in 32 of their own in dogs, conclude that at least periosteum does not always produce bone. In none of their cases did they observe any osteogenetic function. They think that small free bone implants may grow. They consider the periosteum to be a limiting membrane.

TRAUMATIC LESIONS, FRACTURES, DISLOCATIONS, ETC.

Hey Groves,⁵¹ after a large experimental and clinical experience, has reached certain definite conclusions: 1. Not to operate upon any case unless it seems probable that a better result can be obtained than by conservative treatment. 2. If operation is decided upon to employ a method by which perfect anatomical restoration of form can be secured and maintained by mechanical means of such efficiency that at the close of the operation the bone is stronger than before the fracture. He believes that we should not depend upon the frictional grip of nails or screws, but advocates a modification of the bolts and nuts of Prof. De Page (Brussels). 3. If perfect fixation has been thus accomplished he believes the limb should be freely moved as soon as the skin wound has healed,—7-14 days, and that natural function should be resumed as soon as true union has occurred. These conclusions are very similar to those of Sheen,⁵² who as the result of a previous large practical experience without the use of plates and a recent trial of the operative methods of mechanical fixation believes that "no plating is satisfactory unless the bone junction is perfectly firm so that the weight of the limb can be borne by it." Hey Groves considers that Bardenheuer, by his traction methods, Lucas Championnière by the emphasis he has placed upon the evil effects of prolonged fixation, and Lane by the development of efficient local fixation, are responsible for the recent advances in the treatment of fractures. When non-union has occurred he believes that bone grafts are of great value. They should be accurately fitted and retained in position by pegs or sutures. Their failure to stimulate union has been due, in his opinion, to their being loosely inserted.

Albee,⁵³ in reporting fifteen cases of pseudarthrosis in which he has obtained good union in every case, credits his success to the use of his twin motor saws, which accurately cut and mortise the graft, position being maintained by bone pegs or sutures of kangaroo tendon through drill holes. He thinks it is of importance to take the autogenous graft from some healthy bone and not from the eburnated shaft near the seat of fracture.

Bland Sutton⁵⁴ believes that fractures of the external malleolus are frequently unrecognized. When recognized he has found them hard to hold in place and that the displacement was a cause of much pain. He has had good results from the removal of the small loose fragments.

Cotton's⁵⁵ article on astragalus injuries is comprehensive and analytical, and his advice as to treatment is helpful. These fractures, especially when the calcaneo-astragaloid joint is involved, are often very crippling and interfere seriously with the flexibility and painless function of the foot.

Turner Thomas⁵⁶ maintains that the primary cause of "obstetrical palsy" is usually not the

rupture of the brachial plexus, but rather the posterior subluxation of the shoulder joint. In the injury to the joint the plexus may be involved in the adjacent inflammation and at operation found to be imbedded in an abundance of tough adhesion, but he is convinced that the frequent presence of a posterior subluxation and the bent down condition of the acromion process are due to more than a brachial plexus injury. In the nine cases of severe and permanent palsy there was associated a subluxation. In two of the three cases in which there was no subluxation full function has returned. Immediately after birth reduction will be easy, the recognition of the condition being the important thing. He believes that cases in which there is no dislocation or the head of the humerus can be brought into place, offer a good prognosis, and that by exercise the capsule may be stretched to allow full abduction and the muscles induced to functionate. He agrees with Prof. Lange that these cases should not be "left alone."

Menneke⁵⁷ calls attention to the often serious and permanent disabilities resulting from fracture of the acromion process. He is sure the lesion is frequently overlooked. The injury is commonly due to falling on the hand with the arm abducted and the impact of the head of the humerus, as the arm is still further forcibly abducted. Direct blows he thinks are rarely responsible.

Thomas⁵⁸ also reports 18 cases of habitual or recurrent dislocation of the shoulder joint in which he has performed the operation of capsulorrhaphy with good results in all. He prefers the anterior axillary incision and carefully describes the steps and the dangers. He looks upon the lesion as merely a hernia of the joint and believes the operation more safe and effective than that for inguinal hernia. The convalescence is from one to three weeks.

Schwarz⁵⁹ considers that sudden traumatic separation of the upper epiphysis of the femur with immediate noticeable displacement practically never occurs. On the other hand, he believes that slight traumata may lead to a loosening of the epiphysis, which later becomes separated under the weight of the body.

[Ed. Note.—If Schwarz's views are true it is possible that we have here the explanation of certain of the obscure cases of flattened heads associated with coxa vara, which Bloodgood and Legg and others have reported.]

Lehmann⁶⁰ reports thirty-seven cases of injury to the elbow, comprising twenty dislocations, eleven fractures, and six questionable fractures, all in soldiers. There was more or less superabundant ossification about the joint following all these injuries. Many of these bony proliferations show a tendency to absorption if rest is afforded, but their occurrence indicates the necessity in these elbow injuries, even where the dislocation is reduced or no frank fracture is

made out, of rest to the arm and the avoidance of too vigorous early massage.

MISCELLANEOUS.

Chronic Granulating Inflammation of the Bone Marrow. Rost,⁶¹ working in Wilms' clinic in Heidelberg, has been conducting an interesting piece of research work on bone marrow. His work was stimulated by finding what seemed to be a chronic, granulating, non-suppurative osteomyelitis in several sections of bone removed from cases resembling tuberculosis. He then made a large series of experiments on rabbits to determine what influence a number of various substances had on bone marrow. Peptone, bouillon, tuberculin, sugar, olive oil, formalin, alcohol, acetone, magnesia, bismuth, agar, and different fluids gave only a slight reaction, with a small scar containing little connective tissue, which is replaced by bone marrow in a few weeks. Perlmutter dust caused necrosis. Calcium led to the formation of giant cells. Horn dust was followed by rather extensive proliferation of connective tissue and the formation of cysts. Iodoform and Mesbé also caused some connective tissue formation, but the most extensive was caused by the injections of certain carbohydrates, such as Crude Paraffin and American Vaseline. The injection of cocci of decreased virulence caused a granulation tumor which greatly enlarged the bone, together with thickening of the vessels and a perivascular infiltration of round cells. Rost believes that many cases of chronic inflammation in bones of adults much resembling tuberculosis are really cases of chronic non-suppurative osteomyelitis, usually due to the staphylococcus.

[Ed. Note.—The editors have seen several cases of chronic non-suppurative osteomyelitis in which pain and the suggestion of a cavity in the x-ray plate have led to operative exploration. The findings in these cases have been confirmatory of Rost's views. In some of the cases a culture of the staphylococcus albus was obtained. In others there was no bacterial growth. There has been no frank suppuration, but evidence of a chronic low grade inflammatory process.]

Bone Necrosis. Axhausen⁶² points out that the impression which most text-books of pathology give, that bone necrosis and sequestra formation are one and the same thing, is erroneous. Sequestra he believes are the result of infection and occur when a portion of necrotic bone is surrounded by pus and thus separated. Axhausen seems to take it for granted that cortical bone transplants become necrotic, but that the periosteum and portions of the marrow survive, and that the connection between dead bone and living periosteum is the cause of new bone formation.

Syphilitic Affections of the Bones in Children.—Fitzwilliams⁶³ considers that the only difference between syphilis acquired during adult life and syphilis acquired before or at birth is

that in children the slight resistance of tissue allows the disease to run unchecked, irregular in its course, and with a riotous mixture of primary and tertiary symptoms. In his experience, children tolerate mercury well and its administration should be kept up at least two years. For the periosteal pain in tibial periostitis he advocates incision, division of the periosteum, the cutting of a long trench into the marrow and removing the strip of cortex, closing the periosteum and subcutaneous tissues with catgut. This seems to the editors a rather radical and usually unnecessary procedure.

Late Hereditary Syphilis of the Long Bones. Mouchet and Saint-Marc⁶⁴ publish two cases of late hereditary syphilis resembling in the x-ray appearances in the female patient a sarcoma and in the man a multilocular cyst.

[Ed. Note.—Such reports as this we believe are important, since our knowledge of syphilitic bone disease is still very meagre, and as Boorstein has said, far too few cases of syphilis of the bones have been carefully studied and reported, and we are very lacking in our ability to recognize the clinical manifestations. We are coming to realize that its types are very numerous and frequently very confusing, in that they resemble many other non-luetic bone lesions in their Roentgenological appearances.]

Operative Treatment of "Flat Foot." Els,⁶⁵ working in Garré's clinic in Bonn, has been impressed with the good results which have followed tenotomy of the Tendo Achillis in cases of "flat foot." They have followed Hertle's method of open incision, division of the tendon, turning of the divided ends away from each other, the one up, the other down, so that a space of about 4 cm. is left between. Els says that this space is bridged in a few months by a firm scar, tendon-like band. Most of these patients were able to resume their work in about five weeks after their operation, although many of them had been idle for many months previously. The marked diminution of pain even when the deformity was not much corrected he believes to be due to the lessened strain on the astragalo-scaphoid joint, owing to the change of position of the os calcis. Only occasionally are supports necessary, though in the severe cases a bone operation is advised.

[Ed. Note.—We are not confident that this operative procedure is wholly rational or advisable, although apparently it has relieved symptoms in many cases. In Els' cases there was, in addition to the tenotomy a rest of several weeks, which alone frequently relieves symptoms. He states also that the space between the divided ends of the tendon is soon filled in with a firm tendon-like band of scar tissue, which must act very like the tendon. In cases with marked deformity a support was used, and in those with abduction an alteration in the tread of the shoe. While we recognize the frequent association of a short heel cord with foot strain and acknowledge its etiologic relation in certain cases, we see many

cases, ranging from simple pronation strain to marked valgus, in which dorsal flexion to well beyond a right angle is possible. We are inclined to believe that this operation has little to commend it over a simple tenotomy or tendon lengthening and that even these procedures are only rarely necessary in cases of foot strain.]

Under the title of *Etiologic Relation of Posture and Gait to "Flat Feet,"* Harris⁶⁶ holds that improper posture and faulty methods of standing and walking are responsible for weak and flat feet and believes that arch supports should never be worn, and maintains that all cases can be cured by certain exercises which he describes. 1. Rising on heels. 2. Rising on tiptoes. 3. Rising on flexed toes, "grasping." 4. Feet crossed, swaying laterally, etc., etc.

[Ed. Note. We agree heartily with this common relation of bad posture and gait to foot strain. We admit the abuse of arch supports by orthopaedic surgeons as well as by instrument makers and shoe stores, but we consider that the temporary use of some form of support is at times a most helpful means of relieving symptoms and allowing people to lead ambulatory lives. We believe that they should not be prescribed as is so often done as a cure. We should not relax one whit in our exercise treatment and the gradual development of muscles so that a normal shaped flat heel, flexible shanked shoe may be worn with comfort and may aid in the further development of muscles, while the strength and flexibility of the foot is increased. The emphasis at present needs to be laid upon the surprising gains which can be made in this manner by persistent work on the part of the patient even in cases of rigid, painful feet. We do not believe, however, that growing children with bad weightbearing lines, not controllable by altering the tread of flexible shoes, or adults with faulty muscle balances and valgus, should be allowed to walk in positions of deformity and strain. Any exercise treatment administered to muscles already fatigued is less efficient than it should be. Let us be rational and relieve strain in the foot joints by temporary support as we do in other joints. Let us give the devil his due, though at the same time recognizing that what may be a temporary blessing may be a permanent curse.]

Hunt⁶⁷ describes a painful spasm of the lumbar muscles following the exertion of walking or standing; which disappears after a brief period of rest. The motions of the spine may be free and painless and the symptoms are produced only by rhythmic muscular exercise. Hunt considers these symptoms to be due to the same causes as the more generally recognized angina cruris or intermittent claudication and limping, where the cramplike spasm is present in the calf. The arteriosclerotic changes often present in the abdominal aorta in these cases of "Ischaemic Lumbago" seem to account for the condition.

We believe that the example of the American Orthopaedic Association in appointing at its

Washington, 1913, meeting a Commission to Study the Results of Treatment of Scoliosis may well be followed by the appointment of other impartial commissions to study the results of other vexed questions such as arthroplasty, etc. This Scoliosis Commission invited various physicians who were having large clinical opportunities to submit to it six cases, which had been treated by the various methods of forcible correction in plaster jackets. They then selected the clinic of Dr. E. G. Abbott, of the Children's Hospital in Portland, Maine, the clinic of Drs. Lovett and Sever at the Children's Hospital in Boston, the Clinic of Dr. S. Kleinberg at the Hospital for the Ruptured and Crippled in New York, and the clinic of Dr. Z. B. Adams at the Massachusetts General Hospital in Boston, for personal observation. Cards with identical headings as to cause, types of curvature, length and type of treatment and previous condition as shown by records and present condition, were made out by the surgeons for their own cases and independently by each member of the Commission who personally visited the different clinics at the same time and observed the patients and their records. The cases were divided into Grades A, B, and C in proportion to their severity and rigidity and the figures 1, 2, 3, 4, denoting grades of improvement from over-correction to no improvement were agreed upon. Percentages could then be roughly worked out and the Commission found these were practically the same in all their three independently taken observations, though they did not in most cases agree with those of the physician whose cases were being thus critically studied. The report of this Commission was presented at the June, 1914 meeting of the American Orthopaedic Association held in Philadelphia, and has been published in the July number of the American Journal of Orthopaedic Surgery. The great difficulty which the Commission found in arriving at absolutely trustworthy judicial conclusions was the meagerness and lack of standardization of the previous records of the cases. The Commission has been continued and this year is taking its records with X-ray and standardized photographs in the same clinics of a series of cases before treatment, and is planning to take other similar records of the same cases after six months of treatment. We believe this method represents real progress in orthopaedic surgery and is likely to allow an earlier reliable conclusion as to the value of new methods of work than has been possible heretofore.

Reports of Societies.

NEW ENGLAND PEDIATRIC SOCIETY.

C. A. PRATT, M.D., *Pres.*
FRITZ B. TALBOT, M.D., *Sec.*

THE THIRTY-SECOND ANNUAL MEETING OF THE NEW ENGLAND PEDIATRIC SOCIETY WAS HELD IN THE BOSTON MEDICAL LIBRARY, FRIDAY, OCT. 23, 1914, AT 8.15 P.M.

The following papers were read:

MEGALOCOLON AND MICROCOLON WITH CASE REPORTS.

DR. LANGLEY PORTER, San Francisco, Cal.

THE DIFFERENTIATION OF HUMAN AND COWS' MILK BY COLOR TESTS.*

DR. RICHARD S. EUSTIS, Boston.

ASTHMA IN CHILDREN: ITS RELATION TO EGG POISONING.†

DR. FRITZ B. TALBOT, Boston:

* See JOURNAL, page 92.

† See JOURNAL, Vol. clxxi, page 708.

MEGALOCOLON AND MICROCOLON.

By **LANGLEY PORTER, M.D.**, and **ALLANSON WEEKS, M.D.** (From the Medical Dept. of Leland Stanford Jr. University.) It is probable that megalocolon is a more common deformity than is generally thought. The writers have encountered six cases during the past five years.

The symptoms present from birth are great abdominal enlargement, visible peristalsis, obstinate constipation, later anemia and toxemia from fecal retention.

The process may include the entire gut or it may cease at the sigmoid and be replaced by a narrowing. That isolated segments of the large intestine may be affected while most of the gut remains intact and healthy is to be doubted. Fatal collapse can occur from fecal obstruction and this may be brought on by injudicious attempts to empty the bowel.

High fat formulae are not adapted as soap stools give more trouble in all classes of megalocolon than other stools. Enemata are the best means of producing bowel evacuations. Castor oil and magnesia are to be shunned. In older children milk should not be given.

The one measure that promises relief is operative procedure which should be utilized in two or three stages: colotomy with artificial anus; (and this cannot be done too early in the child's life or in the history of the case); lastly, excision of the entire large intestine with anastomosis from the ileocecal region into the rectum; or anastomosis may be done as a second step and resection of the entire colon be made a third operation.

The authors also reported a case of microcolon which illustrates a condition opposite to megalocolon and at the same time furnishes us with an abnormality in the small intestine which in every way parallels the pathological changes found in the large intestine in cases of giant colon. Some reports under the caption stenosis of the colon may have reference to this condition.

DISCUSSION.

DR. J. L. MORSE: I have a case here of this condition which I would like to show to the Society. A child of 25 months, born at full term; nursed for five months, then fed on condensed milk until a year old and since then on an average infant diet. The mother noticed that the abdomen was large at birth and states that in the beginning the enlargement was more noticeable in the lower part of the abdomen and gradually spread upward until it involved the whole abdomen. The baby has always had a good digestion. He has never vomited, but he has never had spontaneous movements. He had from one-half to one teaspoonful of castor oil every other day during the first year and castoria every other day since then. The baby has thriven normally, as you will see, and is in good general condition in spite of his trouble. He was under observation in the Children's Hospital from the third to the eleventh of October. He had no temperature during this time. The tuberculin test was negative. His white blood count was 10,800. He had no spontaneous stools, but with help had daily movements. These stools were medium sized, light-brown, semi-solid, and alkaline. They contained no neutral fat, but a very slight excess of soap and a little starch. That is, his digestion, as shown by the microscope,

was fairly good. He had very definite undulating peristalsis throughout his abdomen. I do not know whether he will show it tonight or not, but he had it a good deal of the time while there. We had him under ether and nothing was discovered except the distinct loops or coils of intestine. He was given a bismuth meal, and we have the plates here which we will show you in a few minutes. These plates show that there is some delay in the emptying of the stomach, but that after the stomach is emptied, the bismuth goes down through the small intestine fairly normally. The plates taken after a bismuth enema show a dilatation of the intestine for some distance up. The bismuth apparently did not, however, come anywhere near going into the whole of the large intestine. I do not think that we gave him enough. The rectal examination was negative.

Dr. William Ladd saw the case with me in consultation and we both felt very strongly, as, of course, everybody does about this condition, that the child's best chance lay in an operation. The mother does not look at it the same way at present, but we hope that she will see the light later.

DR. A. C. EASTMAN: It may be of interest to mention a case I saw a year ago illustrating the border line cases of megalocolon. This child I first saw in consultation one year ago at which time he was 14 months of age. The mother was still nursing him and having difficulty in weaning him. She gave a history of more or less vomiting during his first year in spite of being breast-fed. These attacks were irregular in onset and seemed to come more often in connection with attacks of constipation. After some difficulty he was weaned and for a while kept on a milk diet as there was difficulty in adding any other food. His constipation continued and at times was very stubborn. We added laxative foods to his diet as fast as he would take them, cutting down the quantity of milk, and for a while there seemed to be some improvement. In spite of this every few weeks he would have attacks of constipation which required most energetic treatment with oil, salts and enemata finally to secure a result.

Last May, when 22 months old I saw him again. He weighed twenty pounds, was still having marked constipation, general flabbiness of the muscles and altogether in a rather poor condition. His appetite was very poor and in order to get him to eat they had diminished his laxative diet and put him back on a milk diet. He was given two drops of nuxvomica three times a day and put back on his laxative diet.

In August he had an attack of diarrhea followed within two or three weeks with his previous constipation. His movements were very light colored, of small size and quite frequent. He also cried with apparent pain each time that he had a movement.

In September x-ray plates were taken after a bismuth meal which showed normal muscular stomach tone, the bismuth appearing at the cecum within about four hours. A marked enlargement of the whole colon and rectum was shown and it took nearly 72 hours for the colon finally to empty itself of the bismuth. He was then put on a strict laxative diet and given high oil enemata each night. As a result he had a better movement early in the morning but continued to have frequent small defecations during the day.

In October his general condition was much improved and his present weight is 25 pounds.

Since the date of the meeting he continued to

have considerable pain with his bowel movements which were still quite frequent and small. Rectal examination showed marked spasm of the sphincter with considerable excoriation around the anus. Applications of a mild ichthyol ointment were used for one week with slight benefit. The anus was then dilated under ether and since then his condition has improved steadily, the pain has ceased and the dejections larger and less frequent.

DISCUSSION ON DR. TALBOT'S PAPER.*

DR. H. I. BOWDITCH: How is this egg albumin administered? Is it given as a dry powder?

DR. R. H. SMITH: The egg albumin is prepared by Merck. It can be procured at the drug stores in the powdered form in capsules.

Book Reviews.

Kirkes' Handbook of Physiology. Eighth American Revision. Revised by DR. CHARLES W. GREENE. Illustrated. New York: William Wood and Company. 1914.

The appearance of a new edition of this widely used Handbook of Physiology arouses again the ever-recurring question as to the reason for its popularity as a text-book. It has been adopted by colleges as the basis of undergraduate instruction in physiology, and is used also in medical schools for the instruction of medical students. Whatever may be its merits as a handbook, to be used for reference by persons already familiar with the subject matter of physiology, as a text-book, to be placed in the hands of students, it serves neither undergraduates nor medical students satisfactorily.

To illustrate specifically: A review of histology, occupying 54 pages, is placed near the beginning of the book. The college undergraduate is bound to find this section dull and almost meaningless. The medical student, who, necessarily takes elaborate courses in histology, independently of his work in physiology, will pay no attention to it. Such histology as may properly be included in a text-book of physiology will be grasped more completely by the student if given in connection with the physiological discussions of the tissues described. A very brief general outline at the beginning serves better than an elaborate discussion.

Immediately following the section on histology is a chapter of 45 pages on the chemistry of the body. In this chapter the author plunges

without warning into the most complex conceptions of organic chemistry. This procedure is legitimate in a handbook, but when the handbook is diverted to use as a text-book we are confronted with the fact that its users will be either students without adequate chemical preparation for comprehending these conceptions, or students whose previous or concurrent courses in biological chemistry make the introduction of them into a physiological text-book unnecessary. Much of the material of this chapter is useful for reference. The transfer of all of it, except a general outline, from the body of the work to an appendix, would increase the usefulness of the book as a text-book.

Passing on to the strictly physiological portion, we find in the chapter on blood, under theories of coagulation, Morawitz' complex theory given in detail, accompanied by his bewildering diagram, and immediately afterward Howell's beautiful simplification of the theory introduced, apparently as an afterthought, in such a manner as to becloud rather than to clarify the discussion.

There is no attempt to present the facts of physiology in sequence. The early chapters make familiar mention of matters which are not formally introduced until much later. Thus, on p. 84, enzymes and their catalytic action are mentioned, although no description of them is to be found until page 329 is reached. Similarly, in the discussion of means of hastening coagulation, on page 125, epinephrin is introduced, but the student does not become acquainted with this substance nor with the general conception of hormones until he has read more than three hundred pages further. In this same chapter on blood the phenomenon of coagulation, a matter purely of blood chemistry, is discussed in detail *before* the chemical nature of blood is described. Similar curious inversions of logical order occur throughout the book.

In many portions, notably the sections on the cerebrum, cerebellum, and sympathetic system, the author contents himself almost wholly with statements of the experimental basis for our knowledge of the functions under consideration, leaving the interpretation of the experiments to the reader. This method of presentation is highly satisfactory to the physician or physiologist who wishes to obtain at second-hand the data on which to base his own interpretations. For the beginning student the study of numerous experimental data, not all of equal significance, and unaccompanied by clean cut inferences, is less likely to lead to the desired grasp of physiology than is the reading of a text-book containing fewer descriptions of experiments, but emphasizing the fundamental principles which have been established as the result of the sum total of physiological investigation.

Save for a few errors in the index, the work, on the mechanical side, is satisfactory. The illustrations are well selected, as a rule, and are printed with enviable clearness.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

HOSPITAL EFFICIENCY.

A HOSPITAL accused of being inefficient must of necessity meet a charge which involves a moral as well as a business responsibility. A group of men may lose money by poor business management and still lose it honestly, if the money was their own or is wasted with the approval of those who possessed it. Health may not thus honestly be lost by hospital inefficiency, since it never belongs to those by whom it is lost nor is it wasted with the approval of those who possessed it. Health should not be discussed in terms of dollars and cents.

We are convinced that this charge of inefficiency can with justice be made against certain hospitals. We believe that none desire to be inefficient and we know that the struggle to become efficient is the chief aim of many and the attainment of a few. There is no problem more important, but many of the methods of solution are still in the stage of development.

Without question there should be a group of representative men connected with every hospital who have the best interests of the hospital

at heart, whose duty it is to evolve some standard by which the efficiency of the administration and the different medical services may be judged. The difficulty of picking this representative efficiency committee is admitted to be great. Mistakes will lead to a more careful selection but will not prove the principle wrong. The difficulty of evolving a standard of efficiency especially with reference to the staff, is admitted to be still greater, but with an earnest attempt to understand conditions of work, and by critical, and at the same time friendly, scrutiny of end results, we believe fairly suggestive impressions may be gained. These impressions may be confirmed or disproved by further special observation.

It may be fairly questioned whether at this time there are any hard and fast rules by which standards of efficiency applicable to all hospitals can be determined. Opinions of men differ. These men are equally well qualified to hold opinions and are zealous and earnest in striving to bring about this universally desired result. The report of the committee appointed by the Clinical Congress of Surgeons is important and suggests methods of determination. It should be read by everyone interested in hospitals, certainly by every member of every board of trustees and staff, and it should lead to an immediate consideration of the question by all hospitals.

We as medical men should not only welcome but demand the closest examination by friendly peers of our methods and, with due consideration, of our results. We believe we shall reach the goal of hospital efficiency most quickly by proceeding on the supposition that there is a sincere and general desire for this efficiency, though there may be honest differences of opinion as to methods of attainment. The large attendance at a recent medical meeting where the subject was under discussion was an evidence of the interest of physicians of this and other communities in this question.

Hospitals have a right to request that the investigation be left in their hands, but the public have a right also to demand that this investigation, which so closely concerns them, be thorough and as speedily carried out as the complexities of the problem will allow.

If this demand is not met it is conceivable that an unsympathetic investigation may be instituted, the inevitable injustice of which it is unpleasant to contemplate, and the harmfulness of which it would be difficult to measure.

EXERCISES IN THE TREATMENT OF TABES.

In another column of this issue we publish a paper on compensatory exercises in the treatment of locomotor ataxia. Owing to the development of salvarsan therapy and the recognition of the fact that tabes must be taken out of its old category as a para-syphilitic disease and regarded rather as a late manifestation of the original infection, renewed interest in its treatment has been natural and inevitable. Experience is now sufficiently extensive to make the definite statement that tabes is distinctly influenced by arsenic therapy and it is, perhaps, not too much to say that, if taken in its early stages, it may be cured, or at least rendered stationary for an indefinite period of time. The enthusiasm which has attended this therapeutic outlook has, perhaps, distracted our attention from other useful, if less brilliant, methods of treatment. This is unfortunate, since it must be apparent that however beneficial salvarsan therapy may be, it can by no means be regarded as curative in well-developed stages of the disease. Its influence on pain and the various discomforts incident to the disease is now somewhat universally recognized, but that it can, unaided, overcome a pronounced ataxia of long duration, is not to be expected, and this, certainly, it has not succeeded in accomplishing in any notable degree. As an adjuvant, therefore, to the salvarsan treatment, which, in our opinion, should become a routine measure in practically all cases, stress should certainly continue to be laid upon the principle of training in coördination, originally advanced by Fraenkel and subsequently developed and amplified by Foerster, to which Dr. Swift again calls attention.

The Fraenkel exercises are clearly based upon a perfectly logical conception of the nature of ataxia as essentially a loss or impairment of coördination. It is apparent, therefore, that any means capable of redeveloping or reëducating the coördination becomes an entirely rational method of treatment. Experience demonstrates both its rationality and its practicability. It is quite possible to use these exercises, perhaps in somewhat modified form, in hospital out-patient departments and with unquestioned benefit to the patients, both as regards their general morale and also their actual capacity to coördinate their movements in more orderly fashion. It is possible, as suggested by Dr. Swift,

that the Fraenkel movements lay unnecessary stress upon coördination in the lying position. Foerster, on the other hand, has placed chief emphasis upon the education of equilibrium and is of the opinion that, other things being equal, walking exercises and others in the erect position, lead more quickly to the desired end. In this connection it should be remembered that Fraenkel also insisted upon walking, but only after a somewhat perfect coördination in the less exacting reclining position had been secured. The suggestions made by Foerster and approved by Swift are, undoubtedly, of great practical importance in the treatment of this condition, and other things being equal, it is important to bear in mind that methods which lead to the most direct results are desirable. As a matter of fact, the theories of Fraenkel and Foerster are the same in principle and are supplementary to each other. The important point is, that both lay stress upon the necessity of training and coördination as a distinct method of treatment in one of the most distressing conditions of the disease. It is well to bear this in mind, as suggested before, in view of the possibly over-enthusiastic claims of salvarsan in the treatment of a disease which, if well developed, demands all the resources of our therapeutic art.

THE PROPOSED ABOLITION OF THE OFFICE OF CORONER IN NEW YORK.

For a number of years past, efforts have been made by the more enlightened part of the community in New York to do away with the time-worn, if not time-honored, institution of "crowners' quest," but thus far they have proved unsuccessful. This year there seems to be some prospect that this desirable consummation may be attained.

One ground for this hope is the moral effect which must certainly result from the report by Leonard M. Wallstein, commissioner of accounts, of an elaborate investigation of the system as conducted in New York City, noted in last week's issue of the JOURNAL. According to this report, a continuance of the present system would constitute a public scandal and disgrace, and it is indeed a scathing record which is presented in the following extract:—

"An analysis of 800 inquisition papers made by Dr. Haven Emerson, deputy commissioner of health, shows that in 320 cases, or 40% of those examined, there is a complete lack of evidence to justify the certified cause of death. The incompetent work of the coroners' physicians in the investigation of criminal deaths deprives the community of an absolutely necessary deterrent to crime. So far as the activity of the coroners' office in New York City is concerned, infanticide and skilful poisoning can be carried on almost with impunity. Under the elective coroner system, and in the face of exceedingly difficult conditions surrounding successful criminal prosecution, New York is compelled to get along virtually without aid from the science of legal medicine, a situation that exists in no other great city in the world."

In the field of criminal abortion we learn that the system, instead of serving to detect crime, has become an agency for shielding defendants and concealing criminality. In connection with abortion cases coroners are said to have called or failed to call juries, as best suited their purposes, to have packed juries, and to have intentionally failed to call necessary witnesses or cause police investigation, or to utilize the results of such investigation when made. There is given a long catalogue of the shortcomings and misdoings of the coroners, and a few additional charges may be cited to show the necessity for a radical change. These officers have abused their powers to compel the employment of favored undertakers by the unfortunate families of deceased persons. Civil rights and liabilities have been profoundly affected by the findings of coroners whose action in many instances has been a travesty on justice. Attempts have not infrequently been made to extort sums of money from insurance companies in return for findings in the companies' interest, and until the enactment of the workmen's compensation law the coroner sometimes injured the rights of deceased workmen by helping to establish for employing individuals or corporations a condition of affairs which would relieve them of liability.

The elective coroner in New York represents a combination of power, obscurity and irresponsibility which has resulted in inefficiency and in malfeasance in the administration of the office. With the coroner's constant temptation and easy opportunity for favoritism and even extortion, the report says, with utter lack of supervision and control, and without affording the slightest preparation or training to create in his mind a scientific and professional interest in the performance of his duties, the present system could

not have been better devised intentionally to render improbable, if not impossible, the honest and efficient performance of the important public functions intrusted to this office. Candidates for the position of coroner are nominated "to balance the ticket," to represent a given race, religion, faction or district. Thus, almost every consideration except proper qualification determines the selection, and many of the coroners are absurdly ignorant both as to the legal and the medical aspects of their work. Still another serious objection to the system is the waste of the public funds, as the expense of its maintenance is something like \$175,000 annually, an amount far exceeding what it would cost, under a proper system, to have the work done in an infinitely better manner. The present conditions have long been known, and it is asserted that a remedy would long since have been forthcoming had this not been prevented by purely selfish political considerations. Never before, however, has the public had set before it so complete an exposition of these evils.

Since the completion of the report a case has come to light which further illustrates the charges made in it. A laborer was found dead twelve hours after the janitor of the house where he lodged had helped him to his room in a disabled condition. The police apparently found nothing suspicious about the case and the body was taken to the morgue, where a coroner's physician gave the cause of death as nephritis. When, however, the undertaker who was employed came to examine the corpse he found a large wound at the back of the head. He promptly notified the district attorney's office, and consequently the funeral was postponed and the body ordered back to the morgue. There an autopsy was made by Dr. Charles Norris, director of the laboratories of Bellevue and Allied Hospitals, and Dr. Douglas Symmers, associate professor of pathology in the University and Bellevue Hospital Medical College; when there was found a wound in the back of the head about an inch long and half an inch wide, beneath which there was a linear fracture of the skull, while no evidence of any disease whatever was discovered in the kidneys. The appearances of the injury indicated that it was probably inflicted by a blow such as that by a hammer, and an examination of the man's room showed a considerable amount of blood on the floor, where his body was found.

The recommendations which Commissioner

Wallstein makes include the elimination of the "scandalous jury system and coroners' court" and the substitution therefor of a system of medical examinations by experts similar to that which has worked so successfully in Massachusetts, and he expresses the opinion that the choice between these two methods of fulfilling a public function is "as clear as the distinction between night and day." A bill embodying these recommendations is now being prepared for introduction in the legislature. Similar bills have from time to time been presented at Albany, only to be killed in committee or fail of enactment, but better things are hoped for this, especially as it is believed that it will have the earnest support, not only of the Mayor of New York, but of Governor Whitman, who, from his extended experience as district attorney, has had ample opportunity for observing the deficiencies of the coroner system as a deterrent from crime.

THE IMPORTANCE OF THE PHYSICAL EXAMINATION OF THOSE ATTENDANT UPON INFANTS.

THE untrained attendant received into the family to care for small children and infants, which work necessitates the closest and most intimate contact, often for long periods of time, is practically never examined physically before beginning such duties. In the hospitals, where courses of training of some months' duration are given, such persons are carefully looked over, but the number of persons receiving such training is very small. The problem as a whole does not affect a very large percentage of families, but is none the less an important one. It is estimated that 16% of American families keep one servant or helper and 2% more than one.

The importance of the subject narrows down largely to the consideration of the question of latent tuberculosis or inherited lues. When most persons are engaged in this work, they are at the age when latent tuberculosis is apt to become active, unnoticed perhaps for a considerable period of time, during which, the intimate contact between infant and attendant is kept up. We are, at the present time, more fully aware of the great amount of unrecog-

nized and latent inherited lues in all large communities, through the application of the Wassermann reaction and the use of the x-ray.

It is not then saying too much, with due regard to the fallacy of some eugenic teachings and propaganda, that a person employed in such intimate contact with small children and infants, often for long periods of time, should, on demand, present a certificate of health from a reputable physician, competent to diagnose the above-named troubles. If the expense of such a certificate were too much for the attendant, arrangements could, perhaps, be made with employment agencies in large cities to have the applicants for such positions examined at some large hospital or dispensary, and such certificate issued at a nominal fee, to be renewed at any time, if all is found well. Whether or not the question is settled in this manner, it seems probable that the part of the public directly interested will, when their attention is called to the importance of the matter, have this examination made by their own physician.

DISINFECTION OF SEWAGE FROM TRAINS AND STEAMERS.

WE all recognize the danger of discharged excreta from trains while passing over watersheds and from steamers, especially on the great lakes, when perhaps a few minutes later another one will take in drinking water just where the foul matter from the first has been discharged. The locking of toilet doors on trains while traversing watersheds and while in stations causes considerable inconvenience to passengers, and it is doubtful whether in the case of watersheds the control is absolute. The use of steam for the disinfection of sewage was suggested by Professor Earl B. Phelps in March of last year, and applying this suggestion to the special problem of train and steamer sewage disposal, Leslie C. Frank, sanitary engineer in the Public Health Service, has devised a plan which he has successfully carried out in the preliminary experiments carried on at the Hygienic Laboratory.¹ This plan includes an automatic disinfection of the sewage of a train or steamer by use of heat generated by the power from its propelling engine. There is an insulated container 12 to 15

¹ Sewage Disinfection for Vessels and Railway Trains, Leslie C. Frank, U. S. Public Health Report, January 1, 1915.

ches high and 12 to 15 inches wide, and 4 feet long. The contents are automatically discharged when they reach the boiling point. The device is not limited to steam as a heating agent. For the steam may be substituted electric heating elements, a coil of pipe carrying the exhaust from a gasoline engine, or direct heat from gas or gasoline burners. It is, therefore, apparent that this plan is applicable to the disinfection of sewage from practically all forms of common carriers. It is estimated that the cost of construction uninstalled would be about \$16 for each steamer toilet and about \$15 or \$20 per coach on trains. Using steam as a heating agent, the cost of disinfection on steamers would be \$1 per thousand closet flushes, and on trains 1½ cents per thousand flushes. Estimates of toilet usage indicate that the cost per toilet would be 5 cents a day on steamers and 1½ cents a day on coaches. Thus economy of resources as well as economy of health would be attained by the process thereby deserving the approbation of the business public as well as the professional public.

MEDICAL NOTES.

SMALLPOX AT VERA CRUZ.—Report from the American consul at Vera Cruz, Mexico, on Jan. 7 states that smallpox is now epidemic in that city. The number of cases is not given.

MENINGITIS AMONG CANADIAN TROOPS.—A cable report to Fredericton, N. B., on Jan. 7 states that 30 cases, with 10 deaths, of cerebrospinal meningitis have recently occurred among Canadian troops in camp on Salisbury Plains, England.

PLAGUE INFECTION AND ERADICATION IN NEW ORLEANS.—The weekly report of the United States Public Health Service for Dec. 25, contains a detailed list of thirty cases of human bubonic plague recognized and reported in New Orleans at the time of the outbreak in that city last summer. The last case occurred on Sept. 30. There is also an epidemiologic study of a plague focus in New Orleans by Dr. Charles B. Akin, illustrated by five excellent plates. The importance is emphasized of thorough destruction of all hiding places and thorough closure of all holes in brick walls on premises where plague has been found, to preclude the possibility of house infection.

AUSTRIAN ACADEMY OF SCIENCES.—The Austrian Academy of Sciences has recently awarded

to Professor Wagner von Jauregg the sum of five thousand marks for his research on the etiology of goitre.

HUNTERIAN ORATION.—The Hunterian Oration of 1915 will be delivered on Feb. 15 before the Royal College of Surgeons of England by its president, Dr. Sir Watson Cheyne.

AN IMPORTANT MEDICO-LEGAL DECISION.—On Jan. 7 an important decision was rendered by a New York surrogate to the effect that a child born with a beating heart is alive, even if it never cries, and may inherit property. Hitherto the English common law has held that the first cry legally constitutes life, and that a child which never cries is stillborn. From a medical standpoint, of course, it is primarily the heart-beat which renders a child living, since the fetus is alive while *in utero*. It is a matter of indifference whether oxygenation is obtained through the lung or the placenta. This decision, if sustained, will be of importance in future litigation concerning the reversion of estates falling to children stillborn or dying soon after birth.

FOOT AND MOUTH DISEASE.—Report from Baltimore on Jan. 10 states that a human case of foot and mouth disease has been discovered in a medical student of that city.

Statistics recently published in the January issue of the *Metropolitan* show that the latest European epizootic of foot and mouth disease originated in Russia in 1886.

"Four years later statistics collected in the German Empire showed that nearly half a million head of cattle, more than a quarter million of sheep and goats, and more than a sixth of a million of swine were victims of the disease. In 1871 the infection cost France over seven million dollars; in 1883 England stood a loss of five million dollars.

"Dr. Cope, of the British Board of Agriculture, said at the International Congress of Veterinary Surgeons at Baden-Baden: 'It is true that the foot and mouth disease rarely assumes a fatal character, but the fact that nearly all classes of animals on the farms are susceptible renders the indirect losses much greater in the case of foot and mouth disease than in rinderpest or pleuro-pneumonia, which only affect cattle. In my country, where it existed for at least fifty years, it caused enormous loss—greater than that of all the contagious diseases of animals combined.'

"Dr. Loeffler, an authority, says: 'Foot and mouth disease is spreading more and more every year, and every year it costs the German Empire enormous sums. Necessary measures had been taken with the greatest care; suspected grounds had been closely quarantined; this measure had been extended to whole communes, and even to entire districts; disinfection had been carried out

carefully, and, notwithstanding all this, the disease kept spreading.'

"For eight years England barred the importation of all cattle from countries where the disease was known to have a foothold."

EUROPEAN WAR NOTES.—It is announced that the Harvard Medical School will probably organize an expedition of surgeons, nurses and assistants to take charge of a ward in the American Ambulance Hospital at Neuilly (Paris). Similar expeditions have already been sent by the Jefferson Medical School and by Western Reserve University. To make the project possible a fund of \$10,000 must be raised, and if this can be done, it is hoped that the expedition may sail for France about the first of April.

Sir Frederick Treves has recently presented to the British Red Cross a report of his tour of inspection of its field hospitals in the north of France:—

"This report stated that the value and efficiency of British Red Cross work in France could be well gauged by a visit to the store-shed at Boulogne, by a study of the postings of the fleet of motor ambulances, and by the distribution of the surgeons, nurses, and orderlies in the employment of the Joint Committee.

"The store at Boulogne contained the infinite variety of articles that come under the heading of Red Cross supplies, and the huge depot is described as a model of efficiency. The fleet of motor ambulances Sir Frederick considers to be the most valuable form of voluntary service ever rendered to the Army Medical Department. The ambulances are working everywhere, bringing down patients and returning with stores for the wounded. In the saving of life, the lessening of suffering, and in securing prompt surgical treatment of the wounded, the ambulances have done a work the value of which can hardly be exaggerated. Their efficiency in removing the wounded from the hospital trains to the wards or ships is a revelation to those who have only seen horse or hand carriage in operation.

"The personnel of the Society is dispersed in many directions. Many surgeons are attached to the military and auxiliary hospitals, others are with motor convoys, or with trains or at rest stations. A few are with French troops.

"Valuable work is done at Boulogne by a British Red Cross voluntary aid detachment located in seven railway wagons standing in a siding. There is a dispensing store, a surgery equipped with all necessaries for an emergency dressing station, and a kitchen from which at any hour of the day or night tea or cocoa and other refreshments are supplied to the wounded passing through. Three fully trained hospital nurses are included in the staff, and they render innumerable little services to the wounded. As many as 2300 men have been fed in one day at this station."

On Jan. 16, the total of the New York Belgian relief fund amounted to \$841,645.82; the New York Red Cross fund to \$439,464.01; the American Ambulance Hospital fund to \$304,344.68; the Jewish relief fund to over \$300,000.00; the American Women's war relief fund to \$219,550; the Prince of Wales fund to \$103,513.88; and the Committee of Mercy fund to \$101,028.81.

On Jan. 17, the total of the New England Belgian relief fund amounted to \$177,999.93; the Massachusetts Red Cross fund to \$101,042.02; the Boston branch of the American Ambulance Hospital fund to \$50,996.45; the Boston Jewish relief fund to \$25,181.10; the Boston German relief fund to \$22,326.94; and the Boston Polish relief fund to \$11,734.21.

BOSTON AND NEW ENGLAND.

HOG CHOLERA IN BROOKFIELD.—Report from Brookfield, Mass., on Jan. 7 states that a valuable herd of Yorkshire swine in that town has been found to be infected with hog cholera, of which 10 swine have already died.

MASSACHUSETTS GENERAL HOSPITAL TRAINING SCHOOL.—The graduating exercises of the training school for nurses of the Massachusetts General Hospital were held in Boston on Friday evening of last week, Jan. 15. The principal address, by Miss Mabel T. Boardman, chairman of the national relief board of the American Red Cross, will be printed in a subsequent issue of the JOURNAL. Diplomas were awarded to a class of 54 nurses, two of whom presented graduation essays.

CASE OF TRYPANOSOMIASIS AT TEWKSBURY.—Report from Lowell, Mass., states that on Jan. 1 a patient died of trypanosomiasis at the Tewksbury State Infirmary. The patient was a native of Cape Verde Islands and removed recently from New Bedford, Mass., to Boston. His is the first recorded death from the disease in this state. He was thirty-five years of age.

MILK AND BABY HYGIENE ASSOCIATION.—At a recent meeting of the Boston Milk and Baby Hygiene Association, the directors' report stated that during the year 1914 the Association cared for 4097 babies. The total attendance at the weekly clinics for well babies was 19,673, an increase of 43% over that of 1913. The nurses made 41945 visits to the homes of patients in 1913, and 50,221 in 1914.

ROBERT BENT BRIGHAM HOSPITAL.—At a recent meeting, Dr. Robert B. Dixon and Dr. John E. Goldthwait of Boston were reelected members of the board of directors of the Robert Bent Brigham Hospital.

BOSTON DISPENSARY.—At a recent meeting of the medical staff of the Boston Dispensary, Dr. John D. Adams was elected president, Dr. Frederick C. Cobb, vice-president, and Dr. Elmer V. Barron secretary and treasurer.

A meeting is to be held under the auspices of the Dispensary at Hotel Tulleries on Thursday evening, Jan. 21, at which the principal address, "Dispensaries as a Growing Factor in Curative and Preventive Medicine," will be by Dr. S. Goldwater, health commissioner of New York City and formerly superintendent of Mt. Sinai Hospital, New York. There will also be addresses by Dr. Allan J. McLaughlin and Dr. Edward H. Bradford.

BOSTON HOMEOPATHIC MEDICAL SOCIETY.—At the annual meeting of the Boston section of the Massachusetts Homeopathic Medical Society, on Jan. 7, Dr. Frederick W. Colburn was elected president for the ensuing year. Dr. B. T. Loring was elected first vice-president; Dr. Frederika Moore, second vice-president; Dr. H. E. Diehl, secretary; Dr. Rudolph Jacoby, associate secretary; Dr. E. W. Smith, treasurer; Dr. W. O. Mann, auditor; Dr. O. R. Chadwell, Dr. E. S. Alderwood and Dr. F. R. Sedgley, censors.

BOSTON ASSOCIATION FOR RELIEF AND CONTROL OF TUBERCULOSIS.—A conference on communicable diseases and their relation to the handling of food was held under the auspices of the Boston Association for the Relief and Control of Tuberculosis on Tuesday of this week, Jan. 19, at the Twentieth Century Club, with Dr. Edward Otis as presiding officer. The following ten-minute addresses were presented:

"Dangers in Handling Food by Persons Affected with Communicable Diseases," Allan J. McLaughlin, M.D., state health commissioner; Harry Linenthal, M.D., state health inspector, Boston.

"Tuberculosis in Its Relation to the Handling of Food," Cleaveland Floyd, M.D., director of the patient clinic, Boston Consumptives' Hospital.

"Dangers from Syphilis," Abner Post, M.D., professor of syphilis, Harvard Medical School.

"Some Suggestions in the Employment of Labor," T. K. Cory, vice-president and store manager, William Filene's Sons' Co.; Henry Brahmans, secretary Central Labor Union.

The Association has recently issued a circular letter calling attention to its need for funds in continuation of its work during the coming year. Attention is also called to the Prendergast Camp, where 88 patients are waiting admission to the sanatorium; to the legislative work; the formation of an anti-tuberculosis league; co-operation with the Consumptives' Hospital in obtaining an appropriation to add 125 more beds in that institution; the distribution of 66,000 pieces of educational literature; illustrated lectures and exhibits in hospital clinics and fairs. A great amount of educational work is waiting to be done, and those who realize the importance of preventive measures for public health are asked to aid in the support of the Association.

14. SCHMITTER, F. *Sprue Treated by Emetin Hydrochlorid.*

1. Chapin believes that large institutions for the care of infants are undesirable, that the infant has great need of individual care which can never be given in an institution; where the spread of infections, to which the infant is particularly susceptible, are liable. Boarding out with a trained nurse is the next most desirable condition to that of the home.

2. These authors again speak for the great value of anti-typhoid vaccination. They warn against giving it to pregnant women or during the menses. Severe reactions have never left permanent injuries. The vaccine is in no way an antitoxin but only a preventive. Chronic illness (tuberculosis, etc.), as well as debility from other causes, fatigue and exhaustion, predispose to severe reactions. Injections after intimate or long exposures hasten the onset.

3. Ash's paper bears a timely note of warning in regard to mistaken diagnoses in tuberculosis. The paper is of interest.

4. Carlson believes he has proved that the so-called stomachics or bitter tonics have no influence other than psychic or, increasing secretion of gastric juice.

5. This paper is a thorough and interesting review of this subject to date.

7. Adams' paper is a well thought out analysis of this subject.

9 and 10. These two papers are of very practical interest and are well illustrated by x-ray and pathologic plates.

12. Randall seems to have made a decided advance in detecting the pathology of these cases.

3. TAYLOR, S. *On Some Cases of Anomalous Fever.*
4. BENJANS, T. H. C. *Glycerine in Bromidrosis, with a Note on Military Acids.*

1. In the first Croonian Lecture, Goodall discusses certain aspects in the pathology of mental disorders. He discusses first the dementia precox group of cases and gives a general review of the findings of various observers of pathology, with particular reference to inoculation experiments and the presence of spirochetes and other organisms in the brain cortex. He takes up the subject of disorders of metabolism in insanity, and the value of thyroid administration in mental disorders and in epilepsy with insanity. He presents a very long and elaborate bibliography.

EDINBURGH MEDICAL JOURNAL.

DECEMBER, 1914.

1. *ROSS, J. N. MACB. *Some Observations upon Primary New Growths of the Mediastinum from a Study of Sixty Cases.*
2. *Collective Report. *Perforated Gastric Ulcer.*
3. FOWLER, J. S. *The Nutritive Diseases of Infancy: A Review.*

1. Ross gives an excellent study based on sixty cases of new growths of the mediastinum. Malignant disease of the mediastinum is not so rare as is generally supposed, whereas innocent tumors are very unusual. It is essentially a disease of early middle life, twice as common in males as in females, and seems to be increasing in frequency. A definite history is often found, and is commonly one of malignant disease. Though tubercle bacilli are rarely present in the sputum, there is possibly some relationship between pulmonary tuberculosis and new growths of the mediastinum. The anterior mediastinum is the common seat of origin. Lympho-sarcoma is the commonest form of the disease. The lungs are practically always affected sooner or later, and pulmonary symptoms are generally present. The right lung is much more frequently affected than the left lung; Extrathoracic metastases are very common and often very palpable. Pyrexia, if present, is due to some complication supervening upon, or caused by, the original condition. Microscopic examination of the sputum is rarely of value, although the persistent absence of tubercle bacilli in a case suggesting pulmonary tuberculosis is very significant. Hemoptysis, though moderately common, is rarely severe. A pleural effusion is often present, and is often hemorrhagic, but a hemorrhagic effusion is not pathognomonic of malignant disease. Examination of the fluid is rarely of diagnostic value. A large proportion of lymphocytes is quite as commonly found in a malignant as in a tuberculous effusion.

2. This article on perforated gastric ulcer is a collective report on a series of 247 cases treated in Edinburgh between 1896 and 1913. The data are presented in tabular form. There were 99 cases of gastric and 145 of duodenal perforation. The mortality was reduced from 70% during the period from 1896 to 1898 to 35% in 1909 to 1913. The majority of the patients were between 20 and 25 years of age.

In 146 instances, there was a previous history of indigestion or ulcer. The writers discuss the premonitory signs of perforation, the signs following perforation, and the site of the pain, vomiting, and the site of maximum tenderness and maximum resistance. The operative details and the exact position of the perforation and the conditions found on operation, are also described. Gastro-enterostomy was performed in 29 of the cases.

10. OBENDORFFER, E. *Letters from the Battle Front.*

4. Dysentery has always been associated with the epidemiology of war. It is a hand to mouth infection, usually transmitted by a carrier through foodstuffs or drinking water, and is not caused by one specific organism but a variety of bacteria belonging to the same group. The essential pathological condition is an ulceration of varying severity found in the large intestine and less often in the lower part of the small intestine and appendix. The disease may be mild or rapidly fatal. It usually begins as a diarrhoea which becomes increasingly severe. As many as one hundred and eighty-six stools a day have been noted. The discharges are a first faecal, then contain mucous, pus and blood. Accompanying them is tenesmus and flatulence. Fever is usually absent. The pulse is slow and of poor quality. The urine may contain albumin and casts. Death occurs from exhaustion and is usually sudden. Recovery is gradual, and relapses occur frequently. Good therapeutic results have been reported from polyvalent serum. This can be given intramuscularly or intravenously but is by no means specific. Aside from this, the treatment is symptomatic. Grober advocates the early use of cardiac tonics such as camphor and digitalis, and a rather liberal typhoid diet. Finally, rigid isolation and sterilization must be enforced.

5. Blaschko believes that efforts should be made to check venereal disease in the present war by two methods. Firstly men and women must be closely supervised. When disease is discovered the patients must be hospitalized and kept under supervision until they have recovered. Secondly, Blaschko advocates general education of the soldiers upon venereal diseases and their consequences. For this purpose he has written a small pamphlet for distribution. This states simply that the men under arms owe their lives and health to their country; venereal disease is incapacitating; women camp-followers are a constant menace to the soldier's health. If any venereal disease is contracted Blaschko urges the individuals to report themselves to the physician in charge. [R. F.]

6. Meyer puts the hand in the proper position for writing and then makes a cast. This holds the hand in the proper position and prevents any spasm. This stiff glove is used until the tendency to contracture is over.

7, 8, 9, 10, 11, 12. Hochlaus reports his experiences in 46 cases of tetanus, and concludes by advising first the prophylactic use of serum, as powder in the wounds and subcutaneously; when tetanus is present the intraspinal and intravenous use, together with morphia and subcutaneous use of Mg.SO₄. Kreuter treated 31 cases entirely by intraspinal and intravenous use of large doses of serum, with a mortality of 35% as against other lists of cases showing 57 to 32% mortality. He says the magnesium sulphate and carbolic acid treatment are useless. Müller has seen very little result from the use of magnesium sulphate

and serum, although he uses serum right along. He found very hot baths to be a great help. In two cases he had relief from tracheotomy. Rothfuchs used salvarsan with benefit in four cases. Kühn used luminal, about 1 gm. per day. Alexander gave eight cases 10 gm. of chloral per day in a single day and all recovered; two with 5 gm. died. [E. L. Y., JR.]

4. UNNA, P., JR. *New Experiences in the Treatment of Smallpox Pitting.*

3. Marcuse discusses the x-ray diagnosis of stenosis of the small intestine, with particular reference to the portions between the proximal loop of the jejunum and the terminal loop of the ileum. Filling defects, retention, and changed peristalsis are given as possible but not constant or pathognomonic signs. Emphasis, however, is focused on dilatation of the intestinal loop proximal to the stenosis, which gives an x-ray picture of a ball partly filled with fluid and partly with gas. These hollow balls may persist for 24 hours, and may be so pronounced that they may occasionally be seen without the use of bismuth. Small intestine air bubbles can be easily distinguished from gas in the stomach, duodenum, colon, penetrating ulcers of subdiaphragmatic abscess. The variety of stenosis cannot be accurately determined in the small intestine by this sign, because only the dilated and not the stenosed portion of the gut is seen.

Obituary.

ALBERT VAN GEHUCHTEN, M.D.

DR. ALBERT VAN GEHUCHTEN, professor of the anatomy, pathology and treatment of diseases of the nervous system at the University of Louvain, Belgium, died of acute volvulus at Cambridge, England, on December 9, 1914. He was born in Belgium in 1861 and pursued his medical education in the laboratory of Professor Varnoy and at Berlin and Frankfort. His first publication was in 1886 on the structure of muscle cells, in which he advocated the theory of the unity of cell structure. In 1887 he returned to settle at the University of Louvain, where he had been appointed instructor of anatomy. In 1890 appeared his second publication, a study of the olfactory mucosa of mammals, in which he first definitely entered the field of neurologic research. From this time he published in rapid succession a series of brilliant investigations in his department of science. His neurologic publications have been divided into four groups, which are described as follows in the issue of the *British Medical Journal* for December 26:—

"The first, appearing between 1890 and 1896, embraces a series of important publications bearing for the most part on the structure of nerve centres—the olfactory bulb, the structure of the optic lobes, the nerve cells of the sympathetic nervous system, cerebrospinal ganglia, etc. In this group our present-day conception of the neuron was placed on an unassailable foundation, namely, that the neuron comprises a cellular body, protoplasmic prolongations for cellulipetal transmission, and an axis cylinder prolongation for cellulifugal transmission, both kinds of prolongation having a free termination, the

nerve conduction from one neuron to the other being affected by the contiguity of the end ramifications of the axis cylinder of one neuron to the protoplasmic prolongations of the neighboring neuron. The conception that the neuron appeared as an independent and fundamental unit was the solid basis upon which van Gehuchten built all his later researches on the true origin of nerves, and on the course of fibre bundles in the cerebrospinal axis. In 1897 began van Gehuchten's long and fruitful series of study on methylene-blue staining methods, a report on which he presented to the International Congress of Medicine at Moscow in that year. He found that this method was of greater value in the examination of the more intimate nerve structures and their modifications than that of Golgi, hitherto used, which had the disadvantage of being too coarse. Further research in this direction led to investigations on the phenomenon of chromatolysis, and all these investigations are important as forming the basis on which rested his study of the true origin of motor nerves. They gave rise to a number of works on nervous pathology, and were even applied to the complex study of organic lesions in mental affections, especially in dementia precox, and led to van Gehuchten's interesting discoveries on the pathological anatomy of dementia. He proved that the pathological process of rabies had a special predilection for the sympathetic spinal and cerebral ganglia, producing in the nerve cells of these ganglia primary modifications of a chromatolytic nature as well as secondary modifications due to the active proliferation of the endothelial capsule of the nerve cell, which leads to its destruction, and the formation of characteristic rabid nodules.

"The second group of publications, commencing in 1898, deals with the origin or termination of the peripheral nerves and the tract of certain bundles of neurons in the cerebrospinal axis, and, in these days of confused literature on the subject, form classic models by their compass, clearness and precision, as well as by the value and novelty of their conclusions. All these experimental researches, carried out by section, rupture, or more frequently by the extirpation of the nerve in rabbits, were corroborated by the study of comparative anatomy and embryology of the nervous system and by *post-mortem* investigations. Finally, by the discovery of a new method based upon the phenomenon of direct Wallerian degeneration, van Gehuchten gave an exactitude to the results of his studies of the intra-cerebral or medullary course of the motor nerves and certain central nerve tracts never hitherto attained. This indirect Wallerian degeneration was described by van Gehuchten in an exhaustive report presented to the international Congress of Medicine at Madrid in 1903. He showed that if, instead of dissecting a nerve it was torn out, degeneration followed not only of the peripheral but of the central portion of the nerve, such central degeneration being not

retrogressive but descending, like that of the peripheral portion, this being due not to the direct separation of the nerve itself, but to the atrophy of the cells from which it originated and fatally injured by this violent traumatism. Having identified by this new method each one of the peripheral nerves, Professor van Gehuchten extended his ingenious researches into the complex field of the acoustic and olfactory nerve tracts, the central connections of Deiter's nucleus, the superior cerebellar peduncle, the cerebrolular fasciculus, etc., with most brilliant results. We would especially mention in this connection his study on the inhibitive fibres of the heart, a problem which has puzzled many celebrated physicians, but resolved by van Gehuchten, who directly traced the connection of these fibres to the pneumogastric nerve instead of to the spinal accessory.

"The third group of publications deals with problems of nervous pathology, including studies on the central motor neurone of the pyramidal tract, on acute anterior poliomyelitis in the adult, on the pathogenesis of decubitus, on Babinsky's phenomena, on aphasia and syringomyelia. Of his work bearing on the pyramidal tract the most important is that concerning the mechanism and seat of reflex movement, in which he showed that tendon reflex is independent of muscular tonicity, that section or compression of the medulla is accompanied, not by increase of reflex movements, but by disappearance of both tendon and cutaneous reflexes."

The fourth group of publications includes a dozen anatomies and text-books on the nervous system.

Dr. van Gehuchten was a distinguished clinician as well as a laboratory scientist of eminence. He rendered particularly valuable work in the localization of lesions of the central nervous system. He suggested important methods in the surgical treatment of cerebral and medullary tumors and in trigeminal neuralgia. He also proposed, and successfully accomplished, a less complicated method of resection of the post-radical filaments instead of the posterior nerve roots. He was a brilliant teacher and investigator, and his premature death is a serious loss to science and to his unfortunate University.

Miscellany.

MEMORIAL RESOLUTIONS.

CHARLES SEDGWICK MINOT,
M.D., LL.D., D.Sc.

At the meeting of the council of the American Association for the Advancement of Science held in Philadelphia on December 29, a minute¹

was adopted in memory of Dr. Minot. The minute, which was presented by Professor Cattell and adopted by a rising vote, is as follows:—

"The council of the American Association for the Advancement of Science places on record its sense of irreparable loss in the death of Charles Sedgwick Minot and its appreciation of the value of his services to science, to education and to human welfare. Endowed with the best New England blood and traditions, trained there and in the schools of France and Germany, keen in intellect, wise in counsel, sure in action, sincere in friendship, he devoted his life to the advancement of science, the improvement of education, and the betterment of the agencies on which science and education depend. His contributions to embryology, anatomy and physiology gave him leadership in those sciences; his high ideals of education aided in advancing the standards of medicine in America and in placing the Harvard Medical School in its commanding position. Not only by his original researches, by his masterly books and by his fine addresses and lectures, but in countless other ways, he helped his fellow-workers in science—in the construction of microtomes; in the establishment of a standard embryological collection; in the improvement of bibliographical and library methods; in the unit system of laboratory construction, followed in the beautiful buildings of the Harvard Medical School; in the early development of the Marine Biological Laboratory at Woods Hole; in the Boston Society of Natural History, of which he was president for many years and until his death; in the Wistar Institute for Anatomy and Biology; in the administration of the Elizabeth Thompson Science Fund and the Bache Fund of the National Academy of Sciences; in international relations, as when visiting professor to Germany and in the foreign publication of his books; in the editing of *Science* and of journals of anatomy, zoology and natural history; in the founding and the conduct of the American Society of Naturalists and the Association of the American Anatomists; in the establishment of the convocation week meetings of scientific societies; for us especially by his leading part in the work of the American Association for the Advancement of Science, of which he was secretary of section, general secretary, twice vice-president, president, a constant member of the council, at the time of his death chairman of the committee on policy. In the American Association, as elsewhere, Charles Sedgwick Minot leaves a vacant place which can never be filled. We take up our work sadly in his absence; but we know that it will in all the years to come be more fruitful for the heritage of his service."

¹ Quoted from the *Annals of Science* for Jan. 8, 1915.

THEODORE WILLIS FISHER, M.D.

These resolutions on the death of Dr. Theodore W. Fisher were adopted at a meeting of the Boston Society of Psychiatry and Neurology:—

DR. THEODORE WILLIS FISHER, an original member of this society, was born in Westboro, May 29, 1837, and died October 10, 1914. He was educated in the schools of Medway and Wiliston Seminary and Phillips Academy of Andover, and graduated at the Harvard Medical School in 1861. He was a surgeon of the 44th Regiment in the Civil War. He was appointed superintendent of the Boston Lunatic Hospital in 1881 and resigned from that position in 1895. For several years he examined for the public institutions commissioner of Boston most of the insane committed to the state insane hospitals from that city, and saw many cases of mental disease in consultation. Later he was appointed lecturer in mental diseases in the Harvard Medical School. In the seventies, he was the leading expert in his branch in Boston and was frequently called on to testify as a witness in court. He was active in all matters concerning the welfare of the insane and earnestly advocated a new hospital for the insane of Boston. He largely planned the Danvers State Hospital and the buildings first erected by the Boston Lunatic Hospital at West Roxbury. He belonged to many medical societies and was president of this society in 1893.

He was the author of a number of papers. Among these was one entitled, "Was Guiteau Sane and Responsible for the Murder of President Garfield?" published in the BOSTON MEDICAL AND SURGICAL JOURNAL in 1888. He could speak with some authority on this subject as he was employed as an expert in the Guiteau trial. As showing his interest in medical progress, mention may be made of a paper he published in 1889 on "Cortical Localization and Brain Surgery," and another on "The New Psychology," in 1893. Until the last few years of his life, Dr. Fisher continued to be prominent as an energetic worker in the field of mental disease. Unfortunately for his co-workers, he became disabled and was obliged gradually to relinquish the duties which he had performed so well.

Resolved, That this society wishes to place on record its appreciation of the services performed for many years by Dr. Fisher as a progressive and active leader and teacher in the field of mental disease, and its regret that the last years of his life were rendered hard for him by incapacitating illness. It also wishes to record the loss it feels this society has sustained in the death of a faithful and valuable member and kind friend.

Resolved, That a copy of these resolutions be sent to the family and printed in the BOSTON MEDICAL AND SURGICAL JOURNAL.

WALTER CHANNING,
GEORGE T. TUTTLE,
EDWARD COWLES.

GEORGE DEXTER BULLOCK, M.D.

THE following memorial resolution was adopted by a rising unanimous vote at the latest regular meeting of the Norfolk South District Medical Society:—

GEORGE DEXTER BULLOCK was born in Taunton, December 6, 1859, and died in Weymouth, on his birthday, December 6, 1914. His elementary education was received in his native city, after which he entered the New Hampton Literary Institution, New Hampshire, in 1878, graduating from that institution in June, 1881. He then entered the Jefferson Medical College of Philadelphia, graduating in 1885. Two years later he began the practice of his profession in Weymouth. Dr. Bullock was the son of a physician, from whom no doubt, he inherited many of his nice ethical qualities, which he exhibited in his intercourse with his brother physicians. His successful twenty-seven years of practice in Weymouth were marked by love of his profession by his strict consideration for the rights of his brother practitioners, and his entire honesty with his patients. It could not have been otherwise, for he possessed the qualities of head and heart that are so essential to the fulfillment of such honorable traits. Dr. Bullock was a man of decided opinions, always adhering strictly to that which he thought was right. He was a man of kindly disposition, agreeable to meet, either as a physician or man, and absolutely true to his friends. Our sympathies go out to his bereaved family—widow and daughter—who will mourn him. The community in which he lived will miss him, and the South Norfolk District Medical Society will feel the loss of a valuable member.

J. C. FRASER,

E. N. MAYBERRY,

V. M. TIRRELL,

Committee.

ANGELL MEMORIAL HOSPITAL.

THE new building of the Angell Memorial Hospital for Animals, on Longwood Avenue, Boston, has been recently completed and informally opened, and will soon be occupied for work.

"The hospital is built around a central court for large animals, which enter by the front and are received and taken to various special rooms for appropriate treatment. Most of the novelties of the arrangement are on the first floor level, which is somewhat above the grade of the entrance roadway. The left-hand wing of this first floor is devoted to the offices of the agent and superintendent and the right of the main arched way is the entrance to the business office of the hospital and the clinic for small ani-

mals. The right-hand wing, next to the Harvard Dental School, and the rear wing are also given up to the treatment of larger animals. Midway of the right wing is the horse clinic, comprising an operating room and the soak stall room. This latter is a very important feature, tested by the experience of the Veterinary Hospital of the University of Pennsylvania.

"Operating facilities for large animals are exceptionally complete. One of the most interesting devices is the horse operating table, which consists of a huge tilting leaf of planks. The horse about to be operated upon is made to stand against this leaf in a vertical position and is securely strapped to the leaf, then the leaf is tilted over into a horizontal position, and there is the patient on a proper operating table. After the operation, the leaf or tilt, with the horse still strapped to it, is carried to the surgical ward, where the horse is unstrapped and slid off to a tan-bark floor, where he may recover at leisure from the anesthetic.

"In the middle of the rear wing are the medical wards, cut by brick walls into two sections which are subdivided into stalls. In the back left-hand corner is a roomy contagious ward and towards the front of this ward are two brick enclosed stalls for horses suspected of contagious disease. Still further towards the front of the building is a large tan-bark space 30 by 37 feet, where horses suffering from 'black water,' and some other troubles which lead them to kick may be allowed to lie out and thrash around at their pleasure.

"On the second floor of the wing are several wards for small animals and an exercise room, and in the right wing the operating room for small animals, the bacteriological laboratory, wards with cages for small animals, in the back right-hand corner a kitchen for small-animal food. An open corridor surrounds three sides of the central open court on this level, and not only furnishes more exercise ground but provides various effective ventilation through all the second floor rooms. Exercise yards for small animals have been provided on the roofs of the wings, which may later be raised by an additional story if the work of the hospital requires it. So far, provision has been made for horses and small animals; but the whole basement has been excavated so that there is ample room for dealing with hogs and sheep.

"In the central, or memorial portion of the building, the second story is occupied mainly by the offices of the president and treasurer, the library, and by the marble-paved central corridor, back of which is a memorial hall in which the names of contributors to the fund of the society will be preserved in large books mounted in cabinets. On the top of the central section is the publication department, and directors' room and committee and work room."

LARREY AT WATERLOO.

OF particular interest at the present time is the account of Baron Larrey, the great French Napoleonic surgeon, at Waterloo, and his subsequent treatment and care at Louvain, the history of which appears in *La Chronique Médicale*, written some time before the outbreak of the present European war. Professor Masoin of Louvain is the author of the communication.

"At a late hour in the terrible day of Waterloo, Baron Larry retired at the head of his small surgical force, when suddenly he found his retreat blocked by Prussian soldiers. Not knowing the strength of the column, the corps of physicians attempted to force a passage, but were hurled back by a solid wall of Prussians. The Baron's horse fell, wounded by a musket ball, Larrey receiving two sabre wounds, one on the head, the other in the shoulder, which rendered him unconscious. Coming to his senses after a time, he tried to crawl away, but was seized again by the Prussian cavalry, who subjected him to many brutalities and insults. The wounded Larrey's clothing was removed and his captors, noting its richness and the costliness of his accoutrements, thought they had captured Napoleon himself. Larrey was taken from post to post with this idea, finally being brought before a general who, recognizing the soldiers' mistake, was furious and ordered the unfortunate prisoner to be shot immediately. The firing squad was ready to do its duty, when a surgeon approached to blindfold the prisoner. Suddenly recognizing Larry, whose student he had previously been, the surgeon cried out it was impossible to put to death the great Larrey in such a manner. Evidently, his request for a reprieve was granted, for they set out on the march and Larrey was taken before General Bülow, who sent the prisoner on to the famous Blücher. This proved to be not only lucky for Larrey but resulted in his complete safety, as one of Blücher's sons had been saved by Larrey during a military campaign in Germany. An escort was given and Larrey sent to Louvain for treatment. Here he was under the care of Dr. Michotte, surgeon to the civil hospital, and of Dr. Hubert Vandepoël of the military hospital. The medal of St. Helen was later given to Dr. Vandepoël in recognition of his services to Dr. Larrey. Louvain was proud to have two of her surgeons care for and cure the battle wounds of the famous Larrey."

The first part of the account of Larrey's capture and journey to Louvain is well known to all, but the details of his treatment and stay in the city were, according to the article, not generally known before Professor Masoin's account. The latter's description is so graphic concerning Louvain and the war which caused Larrey's stay there, that one has for a moment a vivid idea that it must be of the present European struggle that one is reading, so nearly does history seem to have repeated itself.

INTRAVENOUS MEDICATION IN THE SEVENTEENTH CENTURY.

It is not generally recognized at what a very early date intravenous medication was practiced, but a recent article in *La Chronique Médicale* gives interesting light on this subject. In a work by Michel Etmuller, published in Amsterdam by Jean Aubie in 1691, the following occurs:

"For some time there has been a new method of introducing remedies into the body by injecting them immediately into the veins, which is known as infusion." He goes on, according to the article, to give the different reasons for which such treatment was given. "The English," said Etmuller, "were the first to practice this method, and it is probable that Voren, at that time a professor at Oxford, was the first to use the method. At the hospital at Dantzic the method was used also, and an intravenous infusion of scammony in guiae was given to a soldier with an inveterate syphilis with ulcerations of the legs and a tumor of the right arm. After the injection, he vomited, but in 24 hours the symptoms disappeared. The ulcers were healed in three days."

How like an account of the present intravenous use of salvarsan this recognized therapy of 220 years ago sounds.

Correspondence.

SURGICAL INSTRUMENTS FOR THE BELGIANS.

Boston, January 9, 1915.

Mr. Editor: I sent around recently to a number of the physicians of Boston a circular, asking for instruments, even of old style, and surgical supplies of any sort, for use on the fields of war and in the army hospitals, especially in Serbia, Russia, and Montenegro. I did this in the belief that even limited personal contributions might in the aggregate reach a number. In response to this appeal I have received quite a number of valuable instruments, some of the best of which were amputating sets and pocket cases, while others consisted of obstetrical forceps and instruments for eye, ear, and throat work, all of which, I am assured, are certain to be welcomed.

I am now writing in hopes that some physicians may be reached to whom the circular did not go, especially physicians in other portions of the state. I would add subcutaneous syringes, if in fair condition, and supplies of morphine or strychnia, heart stimulants, and especially anesthetics are greatly needed; also that if anyone to whose attention this letter may come is acquainted with relatives of physicians who have died, especially former army surgeons, I should be greatly obliged if their attention should be called to this need.

Whatever is sent will be sent promptly, as I understand the vessel is to sail quite soon.

Yours very truly,

JAMES J. PUTNAM, M.D.

WOMEN PHYSICIANS IN MEDIEVAL TIMES.

Boston, Jan. 6, 1915.

Mr. Editor: The following is from a prose translation of "Erec and Enide" by Chrétien de Troyes, among the best-known of old French poets of medieval times. Chrétien wrote in Champagne during the third quarter of the 12th century, 1160-1172. We know, that according to Witherington, in the early Middle Ages, the wounded soldier was first looked after by women.

"Guivret escorted Erec to a delightful, airy room in a remote part of the castle. His sisters, at his request, exerted themselves to cure Erec, and Erec placed himself in their hands, for they inspired him with perfect confidence. First, they removed the dead flesh, then applied plaster and lint, devoting to his care all their skill, like women who knew their business well. Again and again they washed his wounds and applied the plaster. Four times or more each day, they made him eat and drink, allowing him, however, no garlic or pepper. . . . But the damsels cheerfully and gladly showed such devotion in caring for him that, by the end of a fortnight, he felt no hurt or pain. Then, to bring his color back, they began to give him baths. There was no need to mistrust the damsels, for they understood the treatment well."

This poem was based on probable occurrences from Chrétien's knowledge of Arthurian legends and, if true, would certainly show a surprising amount of skill and knowledge for the times.

It is not generally known at what a very early date women took their place in organized medicine, for contemporary with the Lombard, Garloponus, 1050, we find the famous woman physician, Trotula, who occupied the chair of Gynecology at Salerno at this time.

Very truly yours,

WM. PEARCE COUES, M.D.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FROM DEC. 5, 1914, TO JAN. 9, 1915.

December 7, Surgeon J. S. Taylor, detached, *Illinois* to *Nebraska*.

December 8, P. A. Surgeon H. F. Lawrence, temporary duty, Newport Hospital.

December 9, P. A. Surgeon G. E. Thomas, detached, Naval Prison, to Navy Yard, Portsmouth, N. H.

December 12, Asst. Surgeon L. H. Roddis, detached, Marine Advance Base Expedition, Pacific Fleet, to Asiatic Station, via Transport sailing January, 1915.

December 14, P. A. Surgeon K. C. Melhorn, detached Advance Base Expedition, Pacific Fleet, Marines Mare Island, Cal.

P. A. Surgeon R. I. Longabaugh, detached, Third Regiment Marine, San Diego, Cal., to Regimental Headquarters, San Diego, Cal.

Asst. Surgeon L. Leherfed, detached, Marine Advance Base Expedition, Pacific Fleet, to Regimental Headquarters, San Diego, Cal.

P. A. Surgeon W. A. Angwin, to *Monterey*.

Asst. Surgeon P. B. Ledbetter, detached, *Pompey* to Olongapo Station.

Asst. Surgeon W. H. Massey, detached, Olongapo Station, to *Pompey*.

Asst. Surgeon C. S. Stephenson, to Naval Station, Cavite, P. I.

December 15, P. A. Surgeon W. H. Connor, detached, *Dubuque* to *Fulton*.

December 18, P. A. Surgeon E. W. Phillips, to Naval Hospital, Las Animas.

December 18, P. A. Surgeon E. V. Valz, detached, *Minnesota* to home.

P. A. Surgeon J. B. Pollard, to *Minnesota*.

December 22, Medical Director L. L. Von Wedekind, detached, *Solace* to home wait orders.

December 23, Medical Inspector R. M. Kennedy, detached, Naval Dispensary, Washington, D. C., to command *Solacc*.

Medical Inspector C. H. T. Lowndes, detached, Marine Barracks, Washington, D. C., to Naval Dispensary, Washington, D. C.

P. A. Surgeon J. Stepp, detached, Naval Dispensary, Washington, D. C., to Marine Barracks, Washington, D. C.

P. A. Surgeon D. G. Allen, detached, Fifth Regiment Marines to *New Hampshire*.

P. A. Surgeon H. Shaw, to Navy Yard, New York.

P. A. Surgeon L. Sheldon, detached, Naval Medical School, Washington, D. C., to Naval Dispensary, Washington, D. C.

P. A. Surgeon M. E. Rose, detached, Fifth Regiment Marines to Navy Yard, Charleston, S. C.

December 24, P. A. Surgeon E. A. Vickery, detached, Fifth Regiment Marines to Asiatic Station.

December 29, Surgeon W. Seaman, detached, Bureau of Medicine and Surgery, Navy Department to home and wait orders.

December 31, P. A. Surgeon W. A. Angwin, detached, *Monterey* to Naval Station, Cavite, P. I.

P. A. Surgeon Heber Butts, detached, *Wilmington* to *Monterey*.

P. A. Surgeon E. W. Phillips, detached, Naval Hospital, Philadelphia, Pa., to treatment, Naval Hospital, Las Animas, Colorado.

January 5, Surgeon W. Seaman, to Naval Station, Honolulu, T. H.

BELGIAN PHYSICIANS' RELIEF FUND.

Report of the Treasurer of the Committee of American Physicians for the Relief of the Belgian Profession for the week ending January 9, 1915.

F. F. SIMPSON, M.D., *Treasurer*.

APPOINTMENTS.

Dr. Simon R. Klein, professor of histology and embryology at Fordham University Medical School, has been appointed pathologist of the Norwich State Hospital for the Insane.

Dr. Louis Schapiro, of Milwaukee, Wis., has been appointed a member of the International Health Commission of the Rockefeller Foundation, to work in Costa Rica and northern Egypt.

NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The annual meeting of the Society will be held in Sprague Hall, Medical Library Building, on Monday, January 25, 1915, at 8.15 P.M.

MEMORIAL ADDRESSES.

"Dr. Charles Sedgwick Minot," Dr. Richard Clark Cabot.

"Dr. James Gregory Mumford," Dr. William Townsend Porter.

The annual business meeting will be held at 9 P.M. Members of the Suffolk District Medical Society are cordially invited to attend.

E. W. TAYLOR, M.D., *President*.

R. M. GREEN, M.D., *Secretary*.

SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, January 29, 1915, at 8.15 P.M.

The following papers will be read:

1. "Acidosis in Children," Arthur A. Howard, M.D., Boston.

2. "Parenteral Immunization in Conditions of Protein Sensitization," J. L. Goodale, M.D., Boston.

3. "Weaning—Its Relation to Anaphylaxis as Shown by Differential Blood Counts," H. C. Berger, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*

R. M. SMITH, M.D., *Sec'y*.

THE NEW ENGLAND HOSPITAL MEDICAL SOCIETY.—The New England Hospital Medical Society will hold its annual meeting at Boston University, 688 Boylston Street, Boston, Thursday, January 21, 1915.

Business meeting at 7.30. Election of officers.

Lecture at 8 P.M., by Sarah E. Palmer on "Cathedrals of Southern England and of Northern France. Development of Gothic Architecture." Illustrated by original slides.

The annual banquet was dispensed with this year because of the money given by the Society to aid the relief of war refugees in Europe.

ANNA O'SULLIVAN, *Secretary*.

RECENT DEATHS.

DR. FRANKLIN M. COUCH, who died on January 10 at Dalton, Mass., was born in East Lee, Mass., in 1862. After graduating from Amherst College, he received the degree of M.D. from the New York Homeopathic Medical School in 1880. He had practised his profession at Dalton since 1885. He is survived by his widow and by one son.

DR. WILLIAM E. WALKER, of West Charleston, Me., died on January 1, 1915.

DR. LÉON VAILLANT, Professor in the Faculty of Sciences at Montpellier, has recently died at Paris.

DR. NATHANIEL MORTON RANSOM, a Fellow of The Massachusetts Medical Society since 1863, died of arteriosclerosis at his home in Somerville, Mass., January 8, aged 84 years. He was born in North Carver, Mass., on March 8, 1830. He was graduated from the Berkshire Medical College in 1861; lived first in Taunton, Mass., and for twenty-five years in Somerville. He was an ordained minister of the Advent church as well as a physician.

SCHOLARSHIP IN MEDICINE.*

BY THEOBALD SMITH, M.D., LL.D., BOSTON.

WE have come together this afternoon at the close of the day's work to show our appreciation for scholarship and renew our allegiance to the ideals for which it stands. The John Harvard Fellowship represents a kind of honorary degree of limited duration. We assume that the reasons for conferring this distinction will endure throughout the life of the recipient. In other words, we believe that the John Harvard Fellows are to become, in due time, ripe scholars.

Although no two of us may agree upon all the attributes of the genuine scholar of the present day, yet all of us, I am certain, look upon him as devoted to the intellectual life. He does not need to be a hustler, or organizer, or contractor of intellectual labor. The rule of business, not to do anything that some one else can be delegated to do, is not a safe maxim for him. His work, like that of the artist, bears the stamp of his personality. It becomes vitalized and it grows in his hands. It can never be too good for improvement.

The true scholar is probably not aware that he is exercising any leadership, for he is not a conscious leader. He is not the self-constituted head of a so-called school, for that suggests a too close adhesion to unproved doctrines, and is not infrequently exploited for personal and national aggrandizement. He is content with

placing his work on record and leaving it to its fate. The true scholar is not a partisan or advocate because the two or more sides presented by every question for due consideration are quickly detected by his periscopic vision, and he may see little to choose between them. He may at times become partisan to restore an upset equilibrium between contesting sides so that the actual facts may come into better view.

A mere display of absorbed knowledge does not make a scholar. He is not a passive creature. He is continually active in remaking old and creating new knowledge. There is a dynamic element in his make-up. Inactive erudition, often the badge of what has been called culture, is thrown off by him, as ballast is from a rising airship. Too much emphasis has been placed by educators upon the statement so often made, that a university should not teach anything that is useful, for it is apt to be misunderstood. The university teaches things not because they are not useful, but because like Emerson's weeds, their utility has not yet been discovered. The modern scholar, the product of the University, I would then define as one whose motto is the promotion of human welfare. He who in a purely scientific spirit and with the tools of pure science goes forth to struggle for the betterment of his fellowmen, is facing towards true scholarship. This definition will include the scientific worker in medicine. He has been brought into the company of scholars, and he is there to stay.

The young striving student of today may be somewhat discouraged at the seeming indifference and even disdain, manifested by many of his colleagues towards intellectual work. I ven-

* Address to the Students of the Harvard Medical School on the Occasion of the Presentation of the John Harvard Fellowships, Dec. 2, 1914.

ture to suggest several causes at work. The doors of our higher educational institutions are thrown open too wide and the competition between the intellectually fit and unfit has not been severe enough. Our indifferent and unfit students are like square pegs in round holes. They belong elsewhere. Access to educational privileges of the highest order is a very valuable consideration. It is being bestowed without insisting on a due return to society, which largely pays the bills. This cannot but degrade the privilege sooner or later. Another reason may be that human society has been surfeited with the achievements of the mind. We have been living in an age of wonders, due to patient research. Why should not the average man's appreciation become blunted for the time being? The worship of physical force, which has eclipsed scholarly tastes and which breaks forth with equal energy on the field of sport and the field of battle, may be due to the very creatures of intellectual labor, the huge machines of industry which replace the physical labor of giants.

The quiet, unobtrusive character of the thought which must precede all actual achievement conceals the real motive force behind the world's development. It is almost never the scholar who presses the button in order to let the accumulated energy which his researches have brought together, burst forth and perform their marvellous feats before spell-bound multitudes. He and his kind remain in the background and they usually prefer to remain there.

Bagehot, the English economist, quotes Pascal as saying that most of the evils of life arose from "man's being unable to sit still in a room," and he himself deserves quoting on this matter. "If it had not been for quiet people who sat still and studied the sections of the cone, if other quiet people had not sat still and studied the theory of infinitesimals, or other quiet people had not sat still and worked out the doctrine of chances, the most 'dreamy moonshine,' as the purely practical mind would consider, of all human pursuits; if 'idle stargazers' had not watched long and carefully the motions of the heavenly bodies, our modern astronomy would have been impossible, and without our astronomy, our ships, our colonies, our seamen, could not have existed." To sit still in a room, to study, and to think, are the necessary antecedents of the scholar. No wonder that scholarship is distasteful to many who are reaching for its fruits. It is an acquired habit, developed by and necessary to civilization. It is the cement that holds together the social structure. Without it society, which is now completely dependent on material welfare, would fall to pieces.

These and other reasons might be given for the not enviable position of intellectual work and the gross misconception of its true value among the youth of our country today. It was probably always so and will continue to be so.

Perhaps there is one function of the scholar which should be cherished above all others. It is to discover and tell the truth. In spite of our many and increasing agencies for disseminating information, it seems just as difficult as ever, to get at the truth about any given subject. It is not always palatable and has occasioned great disturbances. Many scholars have been compelled to fight and suffer for what they firmly believed to be the truth. Even today the scholar's truth is not always acceptable. He may suffer for revealing it, although in no such spectacular ways as history reports to us. We are just as averse to accepting new truths that do not fit our environment as were the people in earlier centuries.

The young scholar's difficulties are not, as a rule, with inquisitions and adverse criticism, either by his co-workers or the public at large. His chief difficulty is to get a hearing. In the first flush of his discovery of a fact he considers production identical with distribution. But he soon begins to wonder why his new fact travels so slowly. In due time he begins to realize that his discovery, his treatise, is having a struggle, all of its own, to survive among the mass that issues from the laboratory and the clinic. The best may be temporarily eclipsed and this fact should give courage when the first fruits have failed to reach the market. He may console himself with the fate of Mendel's discovery, which lay fallow for nearly fifty years. As time goes on he may find that his productions are not properly valued, some are overestimated, others underestimated, still others wholly disregarded. He should not be disappointed, however, but bear in mind that his work will eventually find its proper level. Its true specific gravity will sooner or later decide its fate.

The scholar's rewards will always be small. The distinguished men who have gone before have not been in the habit of thinking of themselves, and this habit should not be encouraged. In the future ideal state of society when we will be doing our tasks instinctively, when we will say with Luther "I can do nought else, God help me," we shall not be thinking much of ourselves.

But let us return to the John Harvard Fellow in Medicine and speculate a little about his future work. Is it expected of him that he go out of his way and become distinguished for exploits far away from the bedside and the laboratory? Shall he become a prominent literary figure, a historian, or an authority in a non-related science? Undoubtedly, success in these fields will earn for him the name of scholar, but he would not necessarily be a medical scholar. Some have attained the mastery in two distinct subjects, but as a rule one languishes. Today medicine is so inclusive that few may venture into other fields without forfeiting their allegiance to it. I would, therefore, define my ideal of the scholar in medicine as one who makes medical science or

biology, which includes medicine, the foundation of all his undertakings.

I take it for granted at the outset that the John Harvard Fellow is going to do some thing well; that he is going to fit himself to be a part of the great engine of medicine which is doing so much work today for human welfare. This is only a fundamental demand upon all of us to find our place in human society and not to become unadaptable fragments, increasing by so much the already formidable human scrap heap. In our profession, to use a well-known quotation, "The knowledge which a man can use is the only real knowledge, the only knowledge which has life and growth in it and converts itself into practical power. The rest hangs like dust about the brain or dries like raindrops off the stones."

But the scholar in medicine must be more than fundamentally serviceable as a part of a great machine. He must be in touch with all its parts. His horizon must encircle all the activities of medical science. He must be more than aware of the existence of other specialties than his own, and bring to his colleagues sympathy and a strong desire to assist and to accept assistance. The more snugly adjusted and useful he becomes in his own specialty, the more cognizant he must become of the essential importance of other specialties. He must make use of this circumspect knowledge and become constructive. Without master minds, medical specialties are but *disjecta membra*, and medicine a chaos.

After these necessary preliminaries have been satisfied, the real task of the scholar in medicine begins, for the test of scholarly work is that its influence radiate beyond the confines of the special field of his immediate life-work, that it penetrate outward and into human society, that it contribute something to the spiritual and social betterment of his fellow men. More than once have I heard it said by men in private and in public, that their hopes for human society were centred in the vital disclosures of biological and medical research. Each scholar must try to find this major problem for himself, and in the choice and the solution his rank will reveal itself. It must be interpretative, illuminative, and not merely executive work. It must give us theories, creeds, and ideals for human behavior and activities. It must build biological facts and theories out over the depths of human superstition, ignorance, and prejudices, so that we may find the place for the next pier on which to rest human activities that aim toward a complete bridging of this chasm. This I interpret to be the true meaning of ripe scholarship.

Is medicine, which I use here as a term inclusive of all biological research, too narrow to carry on this work?

It is now over half a century since Herbert Spencer made an attempt to build up sociology on biological principles. Economists and sociologists have regarded the result as disappointing. I am inclined to suggest to the scholars in medicine of the immediate future. Why not

take up Herbert Spencer's work? We need today more than ever, some constructive, generally acceptable theory of social organization and government, of the relation of the individual to the whole; of the relative meaning of environment and heredity, of the significance of nations as great groups of units to one another. Have not these problems been solved for us, not once, but many times in the organization of man and the lower animals? The student of medicine is well equipped, for he is studying one of the greatest achievements of coöperative activity. Is there any state, any commonwealth, which holds within itself such profound information on fundamental principles of organization and administration as does the commonwealth of cells, called the human body? Is there any that has been studied so profoundly? The many totally distinct, but inter-communicating groups of units, the intricate mechanism of adjustment between near and distant parts, the checks and counterchecks that maintain due equilibrium of function and repress undue individualistic growth, the economy of effort, the remarkable utilization of energy and many other phenomena of government are being disclosed. May not the scholar in medicine help in giving us as units of the social organism a due appreciation of the identity of the problems involved in both biological and social evolution?

It is one of his special tasks to show us the significance of the great practical work our profession is doing in preventing disease and saving life. He must show us both sides of this great work,—not only its humanitarian aspect, but also its one-sidedness, and teach us what is needed to supplement it so that it may be of real and lasting value. Nothing should escape his analysis and criticism of what is going on in the medical world, so that medicine may continually adjust and readjust its own work to changing social conditions. May he not as a student of a subject which is rapidly learning to replace the treatment of symptoms for a study of the underlying causes or necessary conditions, give us without fear or favor the sequences leading to great human catastrophes or diseases of the social organism like the one we are now passing through?

I am led to this suggestion of a more intimate relation between biological and social sciences because great discoveries which give a new direction to currents of thought and research are not, as a rule, gained by the accumulation of vast quantities of figures and statistics. These are apt to stifle and asphyxiate and they usually follow rather than precede discovery. The great discoveries are due to the eruption of genius into a closely related field, and the transfer of the precious knowledge there found to his own domain. It is not so very long ago when medicine paid but little attention and less respect to the unusually rich field of animal life as a source of information. Today, every department of medicine fills its available working spaces with ani-

mals which are the subject of profound study. The results have revolutionized human medicine within a generation.

I have a firm conviction that the laws governing life are the same whether applied to ourselves as great biological organizations or our still greater social organism. My only fear is that we do not yet know enough of these laws to become trusted advisers in social evolution and regeneration. The task is, therefore, great enough to occupy many a John Harvard Fellow of the future, if he be inclined to assume it. With it before him, he would not be tempted to live a life of double dilentanteism, but a single purposeful existence, because his two-fold task would be really one.

Original Articles.

A STUDY OF NORMAL-LOOKING BRAINS IN PSYCHOPATHIC SUBJECTS.

THIRD NOTE (BOSTON STATE HOSPITAL MATERIAL).*

By E. E. SOUTHWARD, M.D., BOSTON.

Pathologist to State Board of Insanity, Massachusetts; Director of Psychopathic Hospital, Boston; and Bullard Professor of Neuropathology, Harvard Medical School, Boston,

AND

M. M. CANAVAN, M.D., BOSTON.

Assistant Pathologist, State Board of Insanity, Massachusetts (formerly Pathologist to Boston State Hospital.)

FOLLOWING is a third fragment of the study now in progress of the brain side of the so-called functional psychoses. Functional psychoses ought to be such that the brains would show nothing that should not be there, nothing not quite "physiological," nothing not essentially reversible and capable of return to the *status quo*. In order to study functional psychoses, we, strictly speaking, need to find cases without intrinsic brain changes. In the midst of the host of intrinsic and extrinsic changes which a majority of brains in psychopathic subjects shows, it has proved difficult to secure an irreproachable functional series. The more exact and finical the brain examination, the harder is it to secure "normal-looking" brains, although the "changes" and "anomalies" found may have had nothing to do with the particular psychopathy of the given case.

* Being Contributions of the State Board of Insanity, Number 25 (1914). The communication was read in abstract at the meeting of the Norfolk District Society in April, 1914. (*Bibliographical Note*. The previous contribution was by Dr. A. W. Stearns (1914-14), entitled "Out-Patient Work in Massachusetts State Hospitals for the Insane," BOSTON MED. AND SURG. JOUR., Vol. cxcv, November 5, 1914.)

The percentages of normal-looking brains in the series so far studied are as follows and may be considered as roughly true in consideration of the anatomical criteria prevalent in the different laboratories.

Worcester ¹	249	741
Taunton ²	70	450
Danvers ³	235	1000
Westborough ⁴	73	500
	627	2691

To these percentages may be added that of the Monson State Hospital (for epileptics).

Monson ⁵	76	205
---------------------------	----	-----

We wish to communicate the results of an examination of 153 brains at the Boston State Hospital, in which there was, if you please, an intentional bias—a bias towards the Danvers standards of counting all suspicious findings among "abnormalities." We need not repeat that we do not suppose that all the abnormalities found in the majority of this or any other series are directly correlatable with the psychopathic status of the subjects which carried the brains. What we are investigating is the normal-looking residuum.

Among these 153 were found 20 brains of a normal appearance, *i.e.* brains showing no destructive lesions, atrophic, cystic, or otherwise, and no sclerosis (in the sense of tissue induration or gliosis, regarded as of pathological nature). Some cases of basal or other arteriosclerosis and some of chronic meningeal change were counted as normal-looking, because upon careful search no sign of *substantial* brain change could be found.

Adhering in general to Kraepelinian lines in diagnosis, we find these 20 distributed as follows:—

Endogenous deteriorations (dementia precox)	2*	(xix, xx)
Manic-depressive group (3 involution cases included)	6	(xiii-xviii)
Senile and allied organic psychoses ..	4	(vii-x)
General paresis	1	(i)
Symptomatic psychoses	2†	(xi, xii)
Epileptic psychosis	1	(v)
Alcoholic psychoses	2	(iii, iv)
Central neuritis	1	(ii)
Syringomyelia	1	(vi)
	20	

Dementia precox forms (10 cases) almost 7% of the total B. S. H. series (153 cases); it forms 10% of the *normal-looking* series. One brain in five dementia precox brains is normal-looking.

Manic-depressive psychoses (involutional cases included) form (12 cases) about 8% of the *total* series; they form 30% of the *normal-looking* series.

Senile psychoses (with some allied forms) form about 29% of the *total* series; they form 20% of the *normal-looking* series.

* Possibly 3, owing to the possible inclusion of xii.

† Possibly 1, if xii be transferred to dementia precox.

In order to secure, if possible, a *microscopically* normal set of cases—cases not merely normal-looking in the gross, but normal-looking with the microscope—some orienting studies have been made with the microscope. These studies have permitted already the solution of some problems.

I. *Normal-looking brain in general paresis (five months' duration of symptoms)*. Microscopically characteristic (plasma-cells about cortical vessels, cell-losses, gliosis) in various areas. Summary follows (details, clinical and structural to be presented in another "note" in this series).

B. S. H. 10,891. Path. (1912.55). Male. Age at onset and death, 53.

Duration of mental disease, 4 months, 27 days.

Mental disease, *continuous*.

Diagnosis. Never in doubt (Psychopathic Hospital, Boston State Hospital).

Terminal Illness. Bronchopneumonia.

Trunk—Chronic Changes. Trichina spiralis, pleuritis, pericarditis.

Trunk—Acute Changes. Hemorrhage in mesentery, bronchopneumonia, bronchial lymph nodes.

Body length—172 cm. *Brain weight*—1270 grams (Tigges' formula—1376 grams).

Lymph Nodes. Not notable.

Ductless Glands: Pituitary, edematous; adrenals, one diffusely red; testes, do not thread well.

II. *Normal-looking brain in central neuritis (six weeks' duration of symptoms)*. Microscopically characteristic (numerous axonal reactions in various areas) but perhaps not a pure case (since the nerve-cell changes were not all of the axonal type and indeed some seemed to show an admixture of cell-lesions). Southard and Hodskins,⁶ as well as Gay and Southard,⁷ had offered some evidence to show an association between the clinical entity called "central neuritis" and softness of brain. Gay and Southard went so far as to suggest that bacillus coli communis infections of blood or cerebrospinal fluid might be at the basis of the soft brain. Canavan and Southard,⁸ in a paper now in press, found in another series that bacillus coli communis failed to be associated with soft brain, but they found other bacteria capable of splitting laboratory media or of abstracting water from such media.

The present case, as the protocol would show, did *not* exhibit a soft brain; but the brain was described as "tense"—feeling and as entirely filling the dura mater, being especially prominent in the central region (brain weight 1350 gms.). The frontal portion of the pia mater was slightly hemorrhagic, and all the spinal root ganglia presented a curious and unusual appearance of hemorrhage.

Culture from the cerebrospinal fluid yielded bacterium capsulatum (capsule bacillus of Pfeiffer), an organism of the aerogenes group. The blood was sterile. Culture from bronchial lymph node yielded micrococcus aureus and micrococcus roseus.

The total course of symptoms in this patient (44 years of age) was 6 weeks. There is certainly a fair question of the diagnosis. Perhaps the root-ganglion hemorrhages acted to produce reflexly the characteristic movements which are more usually found in "central neuritis."

The histological examination of the hemorrhagic root-ganglia shows hemorrhages in spaces of the dura mater adjacent to the ganglia and small hemorrhages in the peridural fatty tissue. There are no evidences of acute inflammation in the dura mater or fatty tissue. Minute vessels within the proximal portion of the dorsal roots show endothelial nuclei of vesicular and slightly swollen appearance, with at one point a moderate number of mononuclear cells of a vesicular appearance in the adventitia. There are no good examples of lymphocytes in the tissue.

If the clinical phenomena are to be at all related to these peripheral changes, it would seem that they must be largely due to mechanical pressure changes, unless we are to interpret the very slight endothelial changes in the small vessels as toxic.

The Marchi sections show fat in cells within the hemorrhage, but do not show evidences of fat in the nerve fibers.

This case evidently deserves more particular study. For completeness' sake we present data as in other cases of this series.

B. S. H. 12,018. Path. 1913.44. Female. Age at onset and death, 44 years.

Duration before admission, 1 month and 14 days.

Hospital Residence. One day.

Diagnosis. (Melancholia (?))—by outside physicians. (Central neuritis, Boston State Hospital.)

Continued mental illness.

Terminal Illness. Acute interstitial nephritis?

Bacteriology. Heart's blood, negative.

Cerebrospinal Fluid. Bacterium capsulatum.

Bronchial Lymph Node. Micrococcus pyogenes aureus and micrococcus roseus.

Trunk—Chronic Changes. Pleuritis (right) sclerosis of coronaries and aortic valve. Fatty liver, fibroma of uterus.

Trunk—Acute Changes. Hypostatic pneumonia, peribronchial lymphnoditis, follicular colitis, interstitial nephritis.

Body Length—152 cm. *Brain Weight*—1350. (Tigges' formula 1216.)

Lymph Nodes. Peribronchials enlarged.

Ductless Glands: Pituitary negative; thyroid small; adrenals thin. Ovaries firm.

III. *Normal-looking brain in Korsakoff's (alcoholic) psychosis (ten weeks' duration of symptoms)*. *Erroneously diagnosed general paresis*. The erroneous diagnosis was at the Psychopathic Hospital, whose officers chose to discount a negative Wassermann serum test and a negative cytological examination of the liquor cerebrospinalis, and trusted to certain suggestive mental symptoms and reflex-disorders. Upon transfer to the Main Hospital, the case was diagnosed Korsakoff's psychosis, on the basis of the following findings: Pupils unequal, re-

acting to light within narrow limits, and are irregular in outline. Knee jerks, right more lively than left; trouble in locomotion; restlessness; hunger; untidiness; fabrication and miscalling of bystanders.

B. S. H. 11.226. Path. 1913.6. Male. Age at death, 44.

Duration. Two months, 14 days.

No previous attacks.

Terminal Illness. Sudden death, choking and vomiting.

Bacteriology.—Heart's blood negative.

Cerebrospinal Fluid. Cladothrix invulnerabilis.

Trunk—Chronic Changes. Fibrous pleuritis, epicarditis, sclerosis coronaries, endocarditis, aortic sclerosis, pulmonary tuberculosis. Horse-shoe kidney.

Trunk—Acute Changes. Ileitis, injection duodenum.

Body Length—168 cm. *Brain Weight*—1450. (Tigges' formula 1344.)

Lymph Nodes. Negative.

IV. *Normal-looking brain (over-small?) in delirium tremens (five weeks' duration of symptoms) erroneously diagnosed as general paresis, tabetic form.* Microscopic examination showed numerous acute cell changes, but no evidence of general paresis.

It is probable that this brain, weighing but 1010 grams as against a weight calculated by Tigges' formula (8×151) (the body length) of 1208 grams, should be regarded as either hypoplastic or atrophic.

B. S. H. 9.981. Path. (1911.11). Female. Age at death, 35.

Duration of Mental Illness. One month, 4 days. Continuous mental disease.

Diagnosis. Taboparesis (erroneous).

Bacteriology. Heart's blood, streptococci. Cerebrospinal fluid, negative. Right middle ear, bacterium aerogenes group. Mesenteric lymph node, negative.

Trunk—Chronic Changes. Decubitus. Splanchnoptosis, ascites, cystic oöphoritis, epicarditis, hypertrophy of heart. Healed pulmonary tuberculosis, chronic interstitial nephritis, chronic ileitis, uterine growth.

Trunk—Acute Changes. Hemorrhagic-oöphoritis, acute diffuse nephritis, injection lower lobes of lungs.

Lymph Nodes. Mesenteric enlarged.

Ductless Glands. Pituitary negative. Thyroid very small. Ovaries—one cystic, one hemorrhagic, adrenals normal.

Body Length—151 cm. *Brain Weight*—1010 grs. (Tigges' formula 1208.)

V. *Normal-looking brain in epileptic psychosis.* (Epilepsy since infancy, dementia from 18+, death at 38.) Microscopically, numerous cell losses,—not here further considered.

B. S. H. 4810. Path. (1911.26). Male.

Diagnosis. Epilepsy.

Terminal Illness. Bronchopneumonia.

Trunk—Chronic Changes. Emaciation, hypertrophy of heart, decubitus.

Trunk—Acute Changes. Bronchopneumonia, congestion kidneys.

Lymph Nodes. In left groin enlarged.

Ductless Glands. Pituitary, thyroid, adrenals negative, testes negative.

Body Length—150 cm. *Brain Weight*—1460 grs. (Tigges' formula 1200)

VI. *Normal-looking brain in a syringomyelic subject with mental symptoms.* (Special study to be published shortly by Dr. H. I. Gosline.)

B. S. H. 9445. Path. (1911.31). Male. Age at onset of mental symptoms, 39 years. Age at death, 43 years.

Duration of Mental Disease. 42 months, 27 days. Mental disease uninterrupted.

Diagnosis. Organic dementia or general paresis.

Terminal Illness. Acute vegetative endocarditis.

Trunk—Chronic Changes. Decubitus, pericarditis, endocarditis, aortitis, fatty hepatitis.

Trunk—Acute Changes. Acute vegetative endocarditis.

Body Length—162 cm. *Brain Weight*—1355 grs. (Tigges' formula 1296 grs.)

Lymph Nodes. Not enlarged (bronchial).

Ductless Glands. Pituitary, thyroid, adrenals, negative. Testes negative.

VII-X. *Four normal-looking brains in Senile Psychoses.* The microscopic examination of all four, so far as completed, exhibits obvious cell-losses, although three of the brains are considerably overweight, and two of them markedly so.

B. S. H. 9314. Path. (1911.32). Female. Age at onset, 64. Age at death, 66.

Duration. 25 months, 10 days.

Continuous mental disease.

Diagnosis. Senile dementia, senile psychosis (presbyophrenic type).

Terminal Disease. Chronic interstitial nephritis, cardiac hypertrophy and general anasarca.

Bacteriology. Heart—micrococcus xanthogenicus, micrococcus varians, micrococcus rubescens. C.S.F.—micrococcus xanthogenicus, micrococcus luteus, micrococcus rubescens, micrococcus simplex.

Retroperitoneal Lymph Node. Micrococcus pyogenes aureus.

Trunk—Chronic Changes. Slight emaciation, ascites, periappendicitis, hydropericardium, myocarditis, endocarditis, apical tuberculosis (healed), pleuritis, nephritis, perihepatitis, gall stones, passive congestion liver.

Trunk—Acute Changes. Absent.

Lymph Nodes. No change.

Ductless Glands. Pituitary, thyroid, negative; adrenals negative, ovaries cystic.

Body Length—164 cm. *Brain Weight*—1340 grs. (Tigges' formula 1312).

B. S. H. 10.500. Path. (1912.37). Female. Age 71.

Duration of Mental Disease. Seven months, 19 days. Mental disease continuous.

Diagnosis. Senile psychosis.

Terminal Illness. Bronchopneumonia.

Trunk—Chronic Changes. Emaciation, adhesive pleuritis, bronchiectasis, brown atrophy of heart, chronic interstitial nephritis, myoma of uterus, hepatic atrophy, splenic atrophy, arteriosclerosis.

Trunk—Acute Changes. Streptococcus septicemia.

Ductless Glands. Adrenals large.

Body Length—153 cm. *Brain Weight*—1380 grs. (Tigges' formula 1224 grams.)

B. S. H. 10,192. Path. (1913.16) Male. Age at onset, 75. Age at death, 77.

Duration. 21 months, 21 days.

Diagnosis. (Senile psychosis with delusions and deterioration.) (Cerebral arteriosclerosis.)

Terminal Disease. Gangrene of lung and arteriosclerosis.

Bacteriology. Heart's blood micrococcus tenacatus. Cerebrospinal fluid, bacillus formosus.

Trunk—Chronic Changes. Elephantiasis? decubitus, ascites; sclerosis mammary, coronary arteries; thrombosis mesenteric veins; pleuritis, aortitis, healed pulmonary tuberculosis, renal lithiasis, hepatic cysts, hypertrophy of prostate, lipoma.

Trunk—Acute Changes. Fibrinous pleuritis, gangrene of lung, hemorrhages in spleen.

Lymph Nodes. Perioesophageal lymph nodes enlarged. Peribronchial lymph nodes enlarged.

Ductless Glands. Pituitary, adrenals negative.

Body Length—137 cm. *Brain Weight*—1440 grs. (Tigges' formula 1096 grms.)

B. S. H. 10,241. Path (1911.42). Female. Age at onset, 77. Age at death, 80.

Duration—36 months, 22 days.

Continuous mental disease.

Diagnosis. Senile psychosis, simple deterioration.

Trunk—Chronic Changes. Emaciation, edema, decubitus, periappendicitis, perihepatitis, sclerosis majority of vessels. Hypertrophy heart, endocarditis, pulmonary tuberculosis, interstitial nephritis, fibromata of uterus.

Trunk—Acute Changes. Hemorrhagic ascites.

Ductless Glands. Pituitary negative, thyroid small, adrenals plump and large.

Body Length—140 cm. *Brain Weight*—1125 grs. (Tigges' formula 1120 grams.)

XI. *Normal-looking brain in an exhaustion-psychosis of unknown but brief duration.* Orienting microscopic examination of the two prefrontals, superior parietal and calcarine areas, showed cell losses characteristically in the outer layers, but also to some extent in inner layers. The most marked cell losses appear in prefrontals and left superior parietal area. It seems hard to explain these findings on the basis of a lesion of brief duration unless at times a brief or critically acting agent may kill cells in such wise as to provoke little or no neuroglia reaction.

B. S. H. 10,284. Path. (1912.7). Male, aged 43. Age at onset, 42. In Hospital 2 months, 25 days.

Duration before admission, unknown.

Diagnosis. Exhaustion psychosis.

Terminal Illness. Pulmonary tuberculosis.

Bacteriology. Heart's blood, micrococcus cummulus. Cerebrospinal fluid, micrococcus ovalis.

Trunk—Chronic Changes. Sacral decubitus, chronic periappendicitis, sclerosis coronaries, hypertrophy heart, interstitial nephritis, atrophy of liver.

Trunk—Acute Changes. Bronchopneumonia.

Ductless Glands. Adrenals fat. Pituitary edematous. Undescended testicle.

Lymph Nodes. Mesenteric lymph nodes prominent.

Body Length—141 cm. *Brain Weight*—1550 grs. (Tigges' formula 1128 grams.)

XII. *A doubtful case of paranoiac nature, complicated by toxic features.* The orienting sections showed only slight and focal cell losses in the cortex, and for the rest only various marked evidences of cell disease without cell destruction.

B. S. H. 10,416. Path. (1912.41). Female. Age at onset, 50? marked at 59. Age at death, 60.

Duration of Mental Disease. 127 months, 27 days. Mental disease continuous.

Diagnosis. Paranoiac condition. (Toxic?)

Terminal Illness. Pulmonary tuberculosis.

Trunk—Chronic Changes. Emaciation, visceral peritonitis, pleuritis, pulmonary tuberculosis, pericarditis, hypertrophy of heart. Tuberculosis of intestine (ulceration) perioöphoritis.

Trunk—Acute Changes. Thrombus, aorta.

Lymph Nodes. Bronchial and mesenteric enlarged.

Ductless Glands. Pituitary, thyroid, negative; adrenals small, ovaries small.

Brain Weight—1130 grams. (Tigges' formula 1184 grams.)

XIII-XV. *Three normal-looking brains in cases of involution-psychoses.* Orienting examination in these cases similar to XI indicated that XIII was probably a case of brain atrophy, that XIV was possibly an arteriosclerotic dement, (at any rate microscopic changes in this patient of 84 were rich enough) and that XV was quite beyond question a case of brain atrophy.

B. S. H. 7771, 8933. Path. (1911.5). Female. Age 71. Age of onset, 65; age at death, 73.

First Attack. Duration (onset 65), 24 months, 12 days.

Second Attack. Duration (onset 70), 31 months, 11 days.

Diagnosis. Chronic melancholia.

Terminal Disease. Facial erysipelas and bronchopneumonia.

Bacteriology. Heart's blood, bacterium gallinarium. Cerebrospinal fluid: Micrococcus candidans.

Trunk—Chronic Changes. Emaciation, ascites, splachnaptosis, periappendicitis, pulmonary tuberculosis, pleuritis, coronary sclerosis, endocarditis, gall stones, interstitial pancreatitis, fibromata oöphoritis.

Trunk—Acute Changes. Hemorrhagic endometritis, bronchopneumonia.

Lymph Nodes. Cervical lymph nodes calcified.

Ductless Glands. Pituitary negative, thyroid—cystic, adrenals, autolysed, ovaries atrophied.

Brain Weight—1130 grams. (Tigges' formula 1240.)

B. S. H. 4798, 5394. Path. (1912.11). Male. (1) Age at onset, first, 67. In hospital Aug. 2, 1895, to Dec. 16, 1895. Discharged improved.

Diagnosis. Acute melancholia.

(2) Age at onset, second, 70. In hospital, 14 yrs.

Diagnosis. Involution melancholia.

Entire duration of mental disease, 168-3/30 mo.

Cause of Death. Acute dilatation of the heart.

Course of Disease. Interrupted at first, latterly continuous.

Bacteriology. Heart's blood. Micrococcus cremoides. Cerebrospinal fluid, negative. Bladder, bacterium gallinarum. Prostate, bacterium gallinarum.

Trunk—Chronic Changes. Perisplenitis, peri- and hepatitis. Sclerosis—mammary, coronaries and aorta. Fatty myocarditis, hepatitis. Dilatation of heart and two incompetent valves, tricuspid and mitral. Chronic interstitial nephritis with cysts.

Acute Changes. Injection gastric and intestinal mucosa, acute cystitis, pus in prostate—acute splenic tumor.

Lymph Nodes. None enlarged.

Ductless Glands. Thyroid, adrenals very small. Testes, pituitary not notable.

Body Length—172 cm. *Brain Weight*—1430 grs. (Tigges' formula, 1346 grams.)

B. S. H. 9924. Path. (1912.29). Female. Age at onset, 58; in hospital 18-14/30 mo.

Entire length of mental disease, 20-14/30 mo.

Diagnosis. Involution melancholia.

Course of Disease. Continuous.

Terminal Illness. Septic endocarditis with multiple septic emboli.

Trunk—Chronic Changes. Chronic pleuritis, hypertrophy of heart, sclerosis aorta, atrophy of spleen, atrophic uterus, splenic infarction.

Trunk—Acute Changes. Slight hemorrhages in gastro-intestinal tract, thrombus in aorta.

Lymph Nodes. Not enlarged.

Ductless Glands. Adrenals, ovaries, pituitary negative. Testes negative.

Body Length—150 cm. *Brain Weight*—1050 grs. (Tigges' formula, 1200 grams.)

XVI-XVIII. *Three normal-looking brains in manic-depressive psychosis.* Orienting examination in these three cases showed in XVI and XVIII a moderate degree of cell loss and in XVII numerous cell losses, especially in the upper layers. Possibly XVI and XVIII are most nearly normal microscopically of this whole group (with the exception of the dementia precox xx).

B. S. H. 9483. Path. (1911.36). Female. Age at onset, 29 years. Age at death, 31 years.

Duration. One month before admission. Total duration, 19 months, 28 days.

Diagnosis. Manic depressive.

Terminal Disease. Pulmonary tuberculosis and enteritis.

Trunk—Chronic Changes. Emaciation, edema, decubitus, ascites, pleuritis, pericarditis, hydropericardium, heart hypertrophy, sclerosis aorta, anomaly aorta. Pulmonary tuberculosis, intestinal tuberculosis, interstitial nephritis, fatty hepatitis, cystic organ of Rosenmüller.

Trunk—Acute Changes. Absent.

Lymph Nodes. Induration mesenteric lymph nodes.

Ductless Glands. Pituitary plump, adrenals soft, ovaries firm and thin.

Body Length 152 cm. *Brain Weight*—1140 grs. (Tigges' formula, 1216 grams.)

B. S. H. 5884, 6794, 7040, 10594. Path. (1913.29). Female.

(1) Age at onset, 41; in hospital 2 years. Discharged improved. *Diagnosis.* Acute melancholia.

(2) Age at onset, 43; in hospital 4 months. Discharged improved. *Diagnosis.* Folie circulaire.

(3) Age at onset, 43; in hospital 7 years. Discharged to Medfield. *Diagnosis.* Recurrent mania. Manic depressive insanity. In Medfield two years, discharged to Boston State Hospital.

(4) Fifty-two years. In hospital 13 months. Entire duration mental disease, 162-17/30 mo.

Diagnosis. Manic depressive.

Interrupted at first, latterly continuous.

Terminal Illness. Pulmonary tuberculosis.

Bacteriology. Heart's blood, negative. Cerebrospinal fluid negative.

Trunk—Chronic Changes. Emaciation, atrophy of heart, fatty liver, pulmonary tuberculosis, tuberculosis of intestines, lymphatic hyperplasia.

Trunk—Acute Changes. Absent.

Lymph Nodes. Lymph node hyperplasia appendix and cecal nodes. Ductless glands, adrenals negative, ovaries elongated, white, flat.

Body Length—153 cm. *Brain Weight*—1300 grs. (Tigges' formula 1224).

B. S. H. 11312. Path. (1913.7). Female.

First Attack. Age at onset 20 (for one year). Recovered, not in a hospital.

Second Attack. Age at onset, 62 (for two years, 14 days). Age at death, 64.

Diagnosis. "Unclassified," Psychopathic Hospital. Manic depressive, depressed; second attack, Main Hospital.

Terminal Illness. Bronchopneumonia. Several days' duration.

Bacteriology. Heart's blood, streptococcus acid, lactici. Cerebrospinal fluid, bacillus cinctus.

Trunk—Chronic Changes. Corset liver, pleuritis, sclerosis, aorta, coronaries; atrophy of spleen, interstitial nephritis, gall stones, hydropericardium, thickening and swelling right vocal cord, bronchopneumonia, lymphnoditis, vegetative aortitis, pial hemorrhages, aortic thrombus.

Lymph Nodes. Peribronchial enlarged.

Ductless Glands. Adrenals negative, ovaries sclerosed.

Body Length—148 cm. *Brain Weight*—1370 grs. (Tigges formula 1184.)

XIX-XX. *Two normal-looking brains in dementia precox.* Case XIX, with a well marked underweight brain showed also an underweight heart and liver but failed to show any marked evidence of cell loss in orienting examination as carried out in the six selected regions as mentioned under XI. Only after considerable search in further section was any evidence of cell loss discovered, namely foci of cell loss in right second temporal gyrus. Naturally it would be unwise to correlate the clinical symptoms of any case with so exiguous a lesion.

Case XX showed moderate degrees of cell loss in practically all the areas examined. As above stated, Case XX and the manic-depressive cases, XVI and XVIII are the most free of microscopic alterations of a marked degree in the series.

B. S. H. 8663. Path. (1910.9). Female. Age at onset, 42. Age at death, 56.

Duration of Mental Disease. Fourteen years.

Mental disease interrupted.

Diagnosis. Dementia precox.

Terminal Illness. Osteomyelitis.

Trunk—Chronic Changes. Emaciation, decubitus, edema, ascites, pleuritis, hydropericardium, brown atrophy of heart. Endocarditis, thyroiditis, perisplenitis, gall stones.

Trunk—Acute Changes. Splenitis, nephritis, ileitis.

Lymph Nodes. Retroperitoneal lymph nodes. Superficial lymph nodes enlarged.

Ductless Glands. Ovaries atrophied. Pituitary negative. Thyroid atrophied. Adrenals negative.

Brain weight—1100 grams. (Tigges' formula 1200.)

B. S. H. 10,144. Path. (1912.47). Female. Age at onset, 25; in hospital 27 months, 27 days.

Diagnosis. Dementia precox (catatonia). Entire duration mental disease; 28-3/30 mo.

Continuous mental disease.

Terminal Illness. Pulmonary tuberculosis.

Bacteriology. Heart's blood, bacillus antenniformis. Cerebrospinal fluid, micrococcus citreus and micrococcus concentricus.

Trunk—Chronic Changes. Emaciation, edema, decubitus, tuberculous peritonitis, pulmonary tuberculosis, splenic tuberculosis, hepatic tubercles, oöphoritis and salpingitis, fibroma of uterus, hydrothorax, hydropericardium.

Trunk—Acute. Changes absent.

Lymph Nodes. Mesenteric enlarged.

Ductless Glands. Thyroid, adrenals, ovaries, pituitary negative.

Body Length—148 cm. *Brain Weight*—1210 grs. (Tigges' formula, 1184 grams).

CONCLUSIONS.

1. The present is a fragment from more extensive studies tending to settle the question how far mental disease is consistent with normality of brain; and as in previous work from the Worcester State Hospital, so this work from the Boston State Hospital has chosen to begin with normal-looking brains, since these are more likely to be essentially normal than those brains which yield obvious lesions.

2. On comparison with the Worcester percentage of normal-looking brains, viz., about one in three, and the Danvers percentage, viz., about one in four, the present Boston percentage is much lower, viz., about one in eight.

3. We do not deny that some of the lesions found in the *abnormal* brains may have had little or nothing to do with the mental disease which their bearers showed; the point of our research lodges in the endeavor to discover essentially normal brains in subjects of mental disease. There are 20 in 153 examined by uniform methods which gave promise of being microscopically as well as macroscopically normal.

4. One normal-looking brain yielded a chronic-looking exudate, Case I (12.55) which was a case of general paresis of brief duration

(less than five months), clinically certain, showed nerve-cell, and fibre-changes, gliosis and perivascular mononucleosis (including plasma cells) of fairly even degree throughout sections examined. The gross examination yielded opaque points of thickening in the pia mater over the vertex. The dura had begun to thicken and the calvarial diploe had begun to disappear. The brain had not lost more than 100 grams in weight (Tigges' formula).

5. One case yielded evidences of acute perivascular exudate post-pneumonic encephalitis) but the mental picture cannot be regarded as due to the exudate.

6. The suspicion is often uttered that cases not infrequently show fine vascular disease not evident in the gross. No such case has appeared; but there was one (x, 11.42) which, despite coarse changes in the basal vessels, was included in the normal-looking series and microscopically showed slightly marked fine vascular changes with equally marked cortical changes (no infarcts but generalized and focal losses). This case was a female of 80 whose brain weighed 1125 grams, *i. e.* 5 grams above the calculated weight according to body length. It is possible that the brain was slightly edematous—vacuoles among nerve cells (18 hours postmortem, tuberculous peritonitis). The brain was included in the normal-looking series, although on the autopsy table the diagnosis of "general cerebral gliosis" was made (confirmed by the excess of cells in the plexiform layer in virtually every region examined). It may be inquired why a case with basal vascular disease should not be forthwith excluded on the ground that fine changes will be certain to be found; but they are not sure to be found as xiv, 12.11, proved (since in this case there were *gross arterial* changes and *few or no fine* vascular changes).

7. We have accordingly reduced our 20 normal-looking cases to 18 which still give some promise of proving normal on microscopic examination. One of these 18 was a case of epilepsy, v, 11.26, with dementia; and, since the epilepsy began in infancy, it is doubtful whether it should be included in this study. Microscopically in any event, there were numerous evidences of cell-losses.

8. If we exclude this case of epilepsy from the normal-looking numerator of the fraction, we should also possibly exclude 5 other epileptics (or in all 6) from the denominator, yielding a percentage of 11.5 *i. e.* 17 in 147 cases excluding all epileptics and two cases i and x in which the microscope revealed changes which should theoretically yield gross lesions.

9. In a study of the percentage of normal-looking brains, it would be wise also to exclude clear cases of imbecility, of which there were 2 in the series, neither of which yielded a normal-looking brain; this makes a percentage of 11.7% normal-looking brains in a series of 145.

10. In the analysis of this residue of 17 normal-looking brain cases, we must first consider the question of atrophy or aplasia. Eleven cases yielded brain weights above normal, employing Tigges' formula (*i.e.* $8 \times \text{body length in cm.} = \text{probable brain weight}$). Six remaining brains weighed less than normal according to this formula. Of these six, one (Case iv, 11.11) yielded a brain weight, 1010 grams, calculated weight 1208 grams, which should probably make this case fall into the atrophic brain group. The reflex picture and certain other clinical features gave rise to the diagnosis *taboparesis*. The total duration was but one month and four days. The absent knee jerks proved due either to axonal anterior horn cell reactions or to peripheral neuritis (abundant Marchi degenerations); and it is probable that we are dealing with a *Korsakoff's psychosis* (history of previous attacks of alcoholic mental disease not obtained, but possible). Abundant evidence of cell-loss with satellitosis was found in many areas microscopically.

Another case (xv, 12.29) yielded a brain weighing 1050 grams, *i.e.* a calculated loss of 150 grams. This case showed various evidences of atrophy in other organs also, and microscopically a remarkably diffuse cell loss in the cortex. Clinically the case was one of involution melancholia, 59 years of age, of 20 months and 14 days.

12. Case xiii, 11.5, with a calculated brain weight loss of 120 grams was a female of 73 years, with total duration of about 8 years. The microscopic evidences of cell loss were such that this case also must probably be placed in the atrophic group; in point of fact her brain atrophy was probably obscured by increase of weight $8\frac{1}{2}$ days post mortem (brain not palpably soft on account of gliosis).

13. xix, 10.9, with a calculated brain weight loss of 100 grams, showed a small heart (145 grams) and a small liver (1000 grams). This case probably does not belong in the atrophic group, since microscopically there was small evidence of cell-loss. This case of paranoid dementia precox will be considered below. xvi, 11.36, and xii, 12.41, with calculated brain weight losses of 76 and 54 grams respectively, can also hardly be classed as showing important degrees of brain atrophy (see below).

14. One case (vii, 11.31) must be excluded from the present analysis, because total brain sections are in process of making (case of syringomyelia).

15. There remains a group of 12 cases, excluding i, xiv, v from the original 19, *i.e.* i as general paretic, xiv as arteriosclerotic dement, v as epileptic, iv, xv and xiii as having atrophic brains, vi as syringomyelia (analysis unfinished). We accordingly remain with one normal looking brain in twelve.

16. The residue of normal-looking brains, with the above eight omissions, consists of the following twelve:—

Case.	Sex.	Age.	Onset.	Duration.	Diagnosis.
2 (13.44)	F.	44	44	1½ mos.	Central neuritis.
3 (13.6)	M.	44	43	2½ mos.	General paresis? Korsakoff.
8 (12.37)	F.	71	71	8 mos.	Senile psychosis.
9 (13.16)	M.	77	75	22 mos.	Senile psychosis; cerebral arteriosclerosis.
11 (12.7)	M.	43	42	3 mos.	Exhaustion psychosis.
12 (13.41)	F.	60	50	10 2/3 yrs.	Unclassified (paranoia).
14 (12.11)	M.	84	67	14 yrs.	Involution-melancholia.
16 (11.36)	F.	30	29	20 mos.	Manic-depressive psychosis.
17 (13.29)	F.	53	41	13½ yrs.	Manic-depressive psychosis.
18 (13.7)	F.	64	20	2 ÷ 1½ yrs.	Unclassified manic depressive.
19 (10.9)	F.	56	42	14 yrs.	Paranoia or dementia precox.
20 (12.47)	F.	27	25	28 yrs.	Dementia precox (catatonia).

17. Attention is first directed to four cases of mental disease over ten years in duration; these are xix, xiv, xii and xvii.

18. This group of cases in which gross registration of lesions might have been expected, was subjected to orienting microscopic examination:—

xix, 10.9, shows strikingly few evidences of cell loss, but careful search discovered foci of cell loss in the right second temporal gyrus. This case, though of slow evolution and diagnosed paranoia, is thought to have had hallucinations of hearing as well as of sight. The delusions were largely of jealousy and otherwise sexual. One attack of so-called "cerebral congestion" at 40.

xiv, 12.11, involution-melancholia, 84 years at death, exhibited considerable cell loss in outer layers without marked satellitosis. Marked cell loss in calcarine region.

xii, 12.41, unclassified paranoic case, died at 60, showed fairly numerous cell losses.

xvii, 13.29, manic-depressive psychosis, died at

53, showed numerous cell losses, especially in upper layers.

19. According to a principle mentioned in the Worcester analysis, it would be unlikely that induration could register itself in brains undergoing gliosis in less than three months. There were three cases (II, III, XI), of which II was the case of possible central neuritis with marked acute cell changes ample to explain roughly the brief mental disease, III showed numerous acute cell changes probably quite consistent with the mental picture (Korsakoff's psychosis) and XI showed cell losses, perhaps of long standing (although there were overt symptoms for three months only) together with acute cell changes.

20. The group of intermediate duration, three months to three years, comprises 5 cases, XVI, VIII, XX, XVIII, IX. Of these, VIII, age 71, and IX, age 77, attract attention on the score of age: both showed cell losses, in the former focal with perivascular gliosis, in the latter marked diffuse losses. Of the three remaining, two are manic-depressive cases (XVI, 11.36, and XVIII, 13.7) and one (XX) catatonic dementia precox. All three showed moderate degrees of cell loss.

21. Accordingly, it is plain that the search for functional psychoses which shall be above all neuropathological reproach is an exceedingly elusive task and possibly never to be rewarded. In a forthcoming communication we shall deal with the detailed microscopic picture in five of the cases of this series (XII, XVI, XVIII, XIX, XX) since these five appear to be the least likely of all our series of 153 cases to show important microscopic lesions.

THE EMERGENCIES OF EXTRA-UTERINE PREGNANCY AT THE BOSTON CITY HOSPITAL. AN ANALYSIS OF SIXTY-TWO CASES.

By ERNEST BOYEN YOUNG, M.D., BOSTON.

*Instructor in Gynecology, Harvard Medical School;
Junior Visiting Surgeon for Diseases of Women,
Boston City Hospital.*

EVER since the paper of Robb¹ appeared in 1908, the writer has been especially interested in

the question of immediate or delayed operation in the emergencies arising from ruptured extra-uterine pregnancy.

The views expressed by Robb have caused so much discussion that the writer was led to study the cases treated by the Gynecological service at the Boston City Hospital from 1902 to 1913.

This paper is written after the study of 215 cases diagnosed as extra-uterine pregnancy and treated by the gynecological service since 1902, but deals only with 62 real emergencies which presented the symptoms accompanying ruptured ectopic gestation with severe hemorrhage. These 62 emergencies comprise 31 with a previous history, and symptoms typical of ectopic gestation; and yet in many of these the microscope revealed no sign of pregnancy in the tissues examined.

As they presented, however, such objective symptoms as shock, tubal rupture and severe intra-abdominal hemorrhage, there can be little doubt as to causation. Under any circumstances, the indications as to treatment were identical and hence they have been included. Among these 62 emergencies were 2 coincident extra- and intra-uterine pregnancies, 2 repeated extra-uterine pregnancies, and one twin pregnancy in a single tube.

Analysis of Cases. In 5 the age is unstated. In each of the decades from 20-30 and 30-40 years, the numbers are equal,—28 in each; while after 40 years there is only one. There are none under 20 years.

Obstetric History. Of the whole series, 12 women had never borne children, 14 had previously been pregnant once, 13 twice, 6 three times, 6 four times, 8 had been pregnant five times or over, and in 3 this was not recorded.

The time elapsed since the previous pregnancy among 37 women was: 3 years or under, 16; 3-5 years, 13; and 5-15 years, 9.

Of 46 cases, the previous pregnancy terminated normally in 30, 14 miscarried, and 2 had an ectopic pregnancy.

Duration of pregnancy at the time of rupture in 58 women was: under 2 months in 27, from 2 to 3 months in 26, 3 to 4 months in 4, and 4 months in one.

There were 3 early ruptures: 2 at 2 weeks, and 1 at 3 weeks after the last menstruation.

The last case was interesting, as the tube ruptured near the isthmus, opening the branch of the ovarian arch which runs beneath the tube. The enlargement was about one-half centimeter in diameter, and microscopic examination failed to demonstrate a pregnancy. As there seemed to be no reason to doubt an ectopic gestation in this case, it has been included.

Site of Rupture and Tube Affected. The first was definitely stated in 18: isthmus, 11: central portion, 3: outer end, 4.

The left tube was ruptured in 29, and the right in 27.

There were 3 tubal abortions, all on the left side, and no statement in regard to 3.

Pulse. Of 61 patients, the pulse was 100 or below in 12, and between 70 and 80 in 3. In 27 it was above 120,—170 being the highest rate recorded. The remainder varied from 100 to 120.

Temperature. Of 62 women: 29 had a temperature of 98° or below, 40 a temperature of not over 99, and only 9 rose to over 100°.

Two cases entered with temperatures of 101.2° and 104.2°, respectively.

The Blood Counts. As the bulk of our cases have been operated at night, only 16 have the hemoglobin estimated, and in all these, the sudden onset occurred at least 12 to 24 hours previous to operation. In 3 the percentage was below 40, and in 2 of these so low as to be uncertain by the color test. The remainder were 60% or under, with one exception of 80%.

In looking over these cases we find that the rise of hemoglobin in the blood is a slow process, even after the chance of hemorrhage is past. One patient with 50% hemoglobin at the time of operation had no change by the second day, one with 60% no change on the third and only 5% advance on the eleventh day. Another with 50% on admission had only 60% after 20 days, while one, with hemoglobin too low for estimation, rose only to 45% after 3 weeks. In still another, the hemoglobin gained from 60% to 90% in 19 days, but this is exceptional, and in the first eleven days there was a gain of only 5%.

The red count at entrance, in 4 cases, was between 3 and 4 million, while the patient with extremely low hemoglobin, mentioned above, had 1,164,000 and recovered.

The white count was given in 24 cases and varied from 6400 to 32,000; 10 having a count of 10,000 to 20,000, and 11 of 20,000 or over.

No relation of the white count to either the amount of blood lost or the duration of the rupture could be made out, some of the most severe cases having small leucocytoses.

As showing the rise in reds and hemoglobin, the results are given below in a case recently operated but not included in the series:—

Day after operation	3	6	9
Reds	1,888,000	2,424,000	3,200,000
Hemoglobin	30%	45%	65%

Day after operation	12	24
Reds	3,800,000	3,520,000
Hemoglobin	70%	85%

Symptoms. The symptoms, beside those of ordinary pregnancy, may be broadly divided into two groups: first, premonitory; second those connected with rupture. The first were usually subacute and separated from those connected with rupture, or the acute symptoms, by a definite interval during which symptoms were either wanting or of a mild character. In a few cases the premonitory symptoms were acute, and in some were prolonged into those immediately preceding operation.

In 15 of 60 women, however, there were no disturbing symptoms until the time of rupture.

Three of these pregnancies ruptured early: 1 at 6 weeks, and 2 at 5 weeks after the last menstruation, while 2 ruptured at 3 and 3½ months, respectively.

On the other hand, 45 women gave a definite history of suspicious or alarming symptoms for some time previous to the attack for which they entered the ward; if coupled with the acute symptoms which followed and were present on admission.

Premonitory Symptoms were evident in 15 of these from 2 to 7 days before operation, in 27 for from 8 days to 4 weeks, in 2 for 6 weeks, and in 1 for 8 weeks.

These symptoms consisted of:—

(a) *Amenorrhea.* Excluding 6 women who ruptured before the following menstrual period was due, this symptom, with others, was common to 39, and appeared in 54 of the 60 cases with histories obtained.

Of 15 women with amenorrhea as the only symptom before rupture: 6 were over 2 months pregnant, and of these, 2 were 3 and 3½ months, respectively, i.e. about one-third had simply an amenorrhea.

(b) *Abnormal Flowing.* In the 6 early ruptures mentioned in the preceding paragraph, 5 had either an irregular or constant flow, commencing with or shortly after the last regular catamenial period.

In 41 out of the 45 with distinct premonitory symptoms, flowing appeared at various intervals and more often for varying periods before the rupture.

In 20 flow and pain were combined, and 7 flowed without pain.

(c) *Abdominal Pain.* This was a complaint in 25 and was localized by 13 in the lower abdomen.

It was described by 16 as intermittent and sharp, and by 9 as dull and persistent.

In several there were attacks at varying intervals, and in 20 it was accompanied by flowing, as stated above.

Acute Symptoms. The records contain statements concerning acute symptoms in 59 cases.

In 8, these had been manifest from 2 days to 3 weeks before entrance; and in the remainder, under 24 hours.

Sudden abdominal pain was characteristic of the great majority, but in 7 this was an increase of existing or a recurrence of similar less acute attacks. In 2 there was simply increasing weakness and pallor after previous intermittent or persistent abdominal pain, for a period of 3 weeks in one and 6 weeks in another.

Pain was apparently unlocalized in 21—2 stating it to be general.

Pain was localized by 16 in the lower abdomen and by 1 in the epigastrium, while by 21 it was definitely referred to the right or left pelvic region—always on the affected side.

Fainting is mentioned in 23 instances, nausea and vomiting in 5, and chills in 3.

A dark bloody flow from the uterus was often noted, but this is more characteristic of tubal abortions, while in some a boggy feeling was present in the vagina, with dullness, shifting dullness, tenderness and distention. The tendencies of temperature and pulse have been previously given.

Mortality. These cases have been treated by many operators and the walk of life from which the patients have been drawn has not been conducive to good operative results, many being extremely poor subjects for any operation on account of personal habits and a poor mode of life. The total mortality is 24.2%, but 3 died of: cerebral embolus, patent foramen ovale, and infection before admission. With these omitted, the mortality is still 19.3%, but considering the class with which we deal and the condition of many at entrance there seems to be little likelihood of improvement.

Among the 15 women pregnant for the first time, 5 died,—one a tubal abortion.

In 2 of the 5 fatal cases, a chronic salpingitis was reported, and it does not seem improbable that they were infected at the time of rupture from old foci remaining in the pelvis. Three of the 5 died from peritonitis, and 2 from shock alone.

The causes of death in the 15 fatal cases are given below:—

Shock	8
Peritonitis	4
Cerebral embolus	1
Status lymphaticus and patent foramen ovale.....	1
Infection before admission.....	1

Summary. In reviewing these cases it is instructive to note that exactly 50% gave positive evidence of pregnancy. This may have been often due to the poor selection of tissue, but more probably to the destruction and washing away of evidence by the rupture and hemorrhage following.

With one exception, blood was distributed throughout the abdominal cavity, and in a number of instances the fetus was found floating in the blood.

Age had apparently no influence, as the cases were scattered through the child-bearing period, in such a manner as would be expected under normal conditions. Where recorded, the isthmus was definitely the seat of implantation in over 50% of the cases, and in many others the tube was probably in such condition that an exact statement was impossible.

It is also interesting that about one-half the series presented evidences of previous infection of the genital tract, or at least an obstetric history suspicious in this respect.

The cause of the abnormal pregnancy is obscure in a great proportion, for although adhesions were present in many the records do not always speak of them as of long duration, and in some the opposite tube was reported normal. The scarcity of the statements in regard to ad-

hesions is not to be wondered at, when we consider the necessity for speed at the time of operation and the ease with which localized adhesions might be overlooked.

There seems to be some evidence, however, that an inflammatory condition may have been, in most cases, the determining cause, or at least have produced conditions interfering with the processes of conception.

In regard to the pregnancy immediately preceding in 50 women: 30 were delivered at full term, 14 miscarried, 2 had an ectopic gestation, and no history was available in 4.

The remaining 12 of the 62 cases were primiparae.

Of the 30 delivered at full term, 5 showed marked evidence of old inflammatory processes.

In 9 of the 14 miscarrying at the previous pregnancy, from 3 to 5 years had elapsed without conception, while one had 6 miscarriages in succession after an attack of pelvic inflammation 7 years before.

Chronic salpingitis was reported by the pathologist in 4, but no other data were available.

Of the 12 primiparae: 1 had gonorrhea, 2 were single, 2 had chronic salpingitis, and 8 out of 10 women had been barren for from 2 to 9 years after marriage.

Simpson from his exhaustive study of sterility and fecundity concluded that the chance of pregnancy was slight after the lapse of 3 years of married life, during the period when the chance of fecundity was greatest.

In 38 cases the last pregnancy had been from 3 to 5 years previous in 13, from 5 to 15 years in 9, and of the remaining 16, who had conceived within 3 years, 9 miscarried.

The average number of children borne by 54 women of our series at an average age of 31 years, was 2.42; while the average was 3.27 in 100 women taken from the medical records and averaging 31.23 years.

Realizing that figures as to pregnancy are apt to be fallacious, for many reasons, those in the preceding paragraph are given with these limitations in mind.

It may be said, however, that nearly one-half of the cases had either some actual abnormality or some point in their history which would make us suspicious that a pathological condition might reasonably exist.

The 60 cases, in which data were given concerning symptoms, show that prodromal signs were absent in only 25%, and in 75% they were of considerable duration for the most part, and distinct enough to have attracted the attention of a physician had one been consulted.

Among the 60 cases were three of tubal abortion, but they presented nothing in previous symptoms or in acute onset which would differentiate them from rupture; and in fact, with many tubal abortions, there is a considerable amount of damage to the fimbriated extremity.

Amenorrhea was wanting in only slightly

over 10% of 60 cases with data, and these ruptured before the following period was due. Flowing in these cases came on early after the last period and was persistent or irregular, ending in early rupture.

It is such cases which are so often mistaken for an early miscarriage, while with those of longer duration definite warning abdominal symptoms are seldom absent.

Abnormal flowing occurred in almost every case (4 without) as a premonitory sign, and in slightly over 44% flow and pain were combined.

Surprisingly few complained of abdominal pain as an early symptom (55%), and by still fewer (28%) was it localized, and then always in the lower abdomen.

According to this series, comparatively few ectopic gestations rupture without premonitory symptoms. Where sufficient time had elapsed, amenorrhea was always present to warn of a possibility, made more probable by the almost universal abnormal flow. The flow, in turn, was accompanied by pain in nearly one-half, and in 28% this pain was referred to the lower abdomen.

Not one of these cases was diagnosed previous to rupture, so far as is known.

We may also say, that with pain and flowing after amenorrhea, especially when preceded by longer periods without pregnancy, an investigation is always advisable.

The symptoms connected with rupture were such as are ordinarily given in text-books, and as patients entered the hospital only 2 gave difficulty in diagnosis and these were the only mistakes. One, with the uterus embedded in a symmetrical mass of clot, was mistaken for pregnancy. The second was diagnosed as a pelvic inflammation, and died without operation. This case was complicated by a patent foramen ovale and was in extremis.

Pelvic examination has given little aid in diagnosis, although a mass or a doughy feeling in the pelvis has been mentioned. Dullness in the flanks and shifting dullness have been noted in some, but have depended so much on the thickness of the abdominal wall and degree of intestinal distention as to be often of no special aid.

It is in these cases of rupture that the clots form slowly, and are of such a soft consistency as to be made out with difficulty, especially when hampered by the distention, which in itself has often been a mark of severe hemorrhage.

In connection with the appearance, history, location of pain, temperature, and physical examination, diagnosis has usually been clear.

Leucocytosis, when recorded, has been high in the majority and has furnished little aid in differentiating from sepsis, while no relation of the white count could be established to either the amount of blood or the duration of rupture. Some of the most serious had small counts, and one septic case a leucocytosis of only 7900.

The temperature has also not been elevated to

such a degree as to suggest inflammatory processes, except in such cases as have been obviously infected at entrance. This is somewhat at variance with the reports in other series, where the greater number have had a temperature above normal.

The mortality of the series has already been given, and at once suggests the subject of treatment.

At the start, let it be understood that it is not intended to champion the cause of long delayed operations, for with the patient in reasonably good condition, operation at the earliest moment is always best, but from time to time papers have appeared urging immediate operation in every instance. To this view the writer takes exception, believing that the general application of this principle is wrong, and that a more moderate course is advisable.

In the not very distant past all ectopic gestations were treated expectantly, and it was not until 1849 that W. W. Harbert suggested laparotomy for the control of hemorrhage. Rogers in 1866, and Parry in 1876, again urged this treatment, which Tait was the first to adopt in 1883.

From that time to the present, operation has steadily increased in favor, until for the last twenty years it has been the recognized form of treatment, and when and how to operate the only question.

At a meeting of the American Gynecological Association, in 1908, the advisability of immediate, or delayed operation during shock was thoroughly discussed by men of large operative experience, the two factions being about equally divided.

Looking over the literature for the past few years, one finds many series of immediate operations with far better mortality than the present, but few with which it may be compared, as nearly all include tubal abortions—the less severe with the serious emergencies—and nearly all aim to show the necessity of haste. The statistics compiled by McDonald,² and the series of Ladinski,³ Vineberg,⁴ Price,⁵ and others show excellent results for immediate operation; and it is manifestly unfair to refer to statistics of years long past, when abdominal surgery was not understood. It is also evident that the social or racial characteristics of the hospital clientele may have a considerable bearing on both methods and results.

Aside from Robb, who is a strong partisan, and Treub,⁷ no one except Frank has apparently attempted to work out the problem of "delayed" or "immediate" operation with care. Frank's series is valuable because the individuals were treated in this country by one institution, and by both methods. His conclusions, however, as to operation do not seem entirely warranted by his statistics.

Furthermore, the term "immediate" operation, so often seen, is somewhat elastic, referring

generally to the time when the patient was first seen, and not to the time of rupture; nor has it always appeared to indicate an emergency.

The period elapsing between rupture and operation varies widely in our series, and undoubtedly the same conditions prevail elsewhere, therefore the term is inexact. In this discussion, "immediate operation" has reference to the time of hospital admission, but the duration of acute symptoms has usually been hours, and in a few instances, days, before entrance. All, however, were emergencies at the time of operation, and in a condition of shock. With one exception all were operated.

Practically all patients came from the lower strata, where hygienic conditions and habits do not tend to great bodily resistance, and the question arises as to whether immediate operation was best for all, viewed in the light of the ultimate mortality.

Every surgeon sees those emergencies in which the ability of the patient to withstand the extra shock of immediate operation is doubtful, and he is called upon to decide whether the outlook for recovery would not be bettered by delay, and whether delay in his doubtful cases has been justified by the results.

There seems to be no question but that extra-tubal and intra-tubal rupture (tubal abortion) differ in frequency as well as mortality, for McDonald in a series of 1607 cases, found only three extra-tubal to every seven intra-tubal ruptures, while in the 215 cases operated on the service, rupture was related to abortion as 1 to 3.7.

Intra-tubal rupture, or tubal abortion, is generally characterized by repeated small hemorrhages, which eventually build a laminated clot. This circumscribed irritation of the peritoneum results in a mass of blood surrounded by adhesions, the pressure of the blood in the sac appearing itself to help control further bleeding, even though smaller hemorrhages occur from time to time. For this reason tubal abortions seldom furnish emergencies, as is evidenced by only three grave operative cases among the one hundred and fifty tubal abortions which have been treated by the gynecological service at the Boston City Hospital, and only two immediate operations in the series of Frank,—one of these without free blood in the abdomen.

The reaction of the peritoneum to these localized hemorrhages indicates very conclusively that with the sudden introduction of even a moderate amount of blood into the peritoneal cavity, varying degrees of peritoneal irritation and shock must follow. Our series apparently shows that few women die primarily of hemorrhage, as in only two of the sixty-two emergencies was active bleeding found at operation, and the majority reached the hospital on an average of eight to ten hours after rupture. That the condition of these acute cases is not due en-

tirely to the loss of blood, is borne out by the fact that the shock, rate and character of the pulse are not always in proportion to the blood lost, and that similar symptoms appear after the sudden rupture of the larger ovarian cysts, when there is little loss of blood. One of Frank's cases, with a pulse of 96, was in marked collapse from rupture alone, without much loss of blood, and one of the emergencies at the Boston City Hospital had a pulse of 72, with the abdomen filled.

It is also the writer's observation that the peritoneum of different individuals reacts in varying degrees, even where conditions seem identical,—blood in one apparently causing few, in another many, adhesions. For the same reason, the shock may be profound with a comparatively small hemorrhage. Furthermore, the ability to withstand operation after severe accidents differs as regards both individuals and races.

Using the hemoglobin as a rough estimate of the extent of bleeding, with any considerable amount of blood in the peritoneum, neither prostration nor pulse-rate or volume has the reasonable relation to the hemoglobin percentage which might be expected in patients of apparently equal physical vigor, although it is true we do not know the exact conditions at the start. Greater prostration is often manifested after a comparatively small hemorrhage.

Estimation of hemoglobin and blood corpuscles immediately after hemorrhage shows no special change, but after six to twelve hours, fluid is absorbed from the tissues, and the percentages lowered. Since both red count and hemoglobin appear to undergo slight changes during the first few days after operation, the fluid content of the blood has seemingly adjusted itself temporarily by the time these women reach the hospital, and on this account salt solution should be preferably given in such a manner as to be slowly absorbed, if the conditions warrant delay, and only rarely by intravenous injection. Women who have been treated without intravenous injection appear to make better recoveries and to have a less lasting anemia, even where emergencies seem of equal gravity.

It has never been possible for the writer to perform a transfusion, but in the only two which it has been his fortune to follow after operation, the bettered appearance has promptly disappeared after the first two days, and the pallor markedly increased, showing no advantage over the use of salt solution.

Experience, and a review of these emergencies, leads the writer to believe that it is *shock* not previous hemorrhage, which is the cause of death in those grave cases which succumbed shortly after operation, and that the "immediate" operation is the last straw.

It seems fair to assume that a patient suffering from shock, after pain and hemorrhage, will be more or less worn by an ambulance trip with stretcher bearing at both ends, to say nothing of

the psychic disturbance attendant upon probable operation. To add indiscriminately at this unfavorable moment the extra shock of anesthesia and an abdominal section, appears to the writer in certain cases extremely ill advised. The further decrease of resistance, due to operation, may also take away the ability to cope with organisms which under ordinary circumstances would be innocuous. Peritonitis following operation in such cases is often of a low grade, and in a number of cases it has probably arisen from a previous pelvic infection.

Most patients reach us hours after rupture, and as among sixty-one operative cases, only two were found with active bleeding noted; in taking the chance of hemorrhage, for a few hours at least, we are assuming no greater risk than in adding the shock of operation to that which already exists, as well as the possibility of infection in a state of very low bodily resistance.

It has also been said that patients are upon the "rebound" by the time the hospital is reached. This is true of some, but in others the opposite is equally true; and with the latter, reasonable delay allows opportunity to recover from the effects of transportation, preparation for operation, etc. In every very severe case, under careful supervision, delay should be extended, if possible, to include a reasonable recovery from shock. To this statement only one exception should be made,—the suspicion of active hemorrhage.

The pulse rate may rise slightly, but if the character improves and the rate steadies, no uneasiness need be felt on this account, while in many the rate will diminish after a short rest. Each case, however, must be considered on its own merits; and habits of life, race, and previous history mean something in addition to physical examination.

In the previously mentioned series of Frank, there were 42 ruptures, 21 of which were operated at once, and 21 "observed" before operation.

Of 77 operative cases in his list, including ruptures, abortions, hematoceles, etc., only 24 were operated immediately, including two tubal abortions and one hematocele. Four cases, comprising two ruptures, one hematocele, and one abortion, has no free blood in the abdomen, so that immediate operation was required in only twenty. The only deaths in the whole series were two operated in shock, and one septic hematocele.

Trenb,⁷ in 1908, published 151 cases (including tubal abortions) treated by deferred operation, excepting those with alarming symptoms, with a mortality of three.

Aside from three, dying of causes not directly connected with operation, there are eight of our own series who died of shock, and four with peritonitis,—all operated at once. Some of these, the writer believes, would have lived had intervention been delayed, and in others, peri-

tonitis might have been avoided by a more deliberate operation.

In no rupture has death resulted where operation has been delayed, by the writer, on account of the poor condition of the patient, but he regrets several who died as the result of an operation, undertaken during shock, for what was thought might be persistent hemorrhage.

As has been said before, the differences of the classes from which various hospitals draw their patients and the character of the emergencies received, renders it difficult to make fair comparisons, or to lay down rules suitable for all. When delay has been fairly tried, many serious extra-uterine emergencies have been tided over the critical period of shock, and have been operated successfully. Judging from the series upon which this article is based, and upon others which approach the matter without bias, the effect of an operation during shock is as much to be feared as continuance of hemorrhage, and delayed operation seems well suited to some, and immediate operation unnecessary for all.

On the side of the surgeon it often requires more courage to wait than to proceed immediately, but from the patient's standpoint, the teaching that "immediate" operation is always necessary is decidedly dangerous.

Tubal abortion, with its few emergencies and small mortality, is much more frequent than rupture, and not a few of the former will be treated under poor surroundings by the incompetent, to say nothing of the real emergencies which demand still greater judgment and skill. For this reason alone, care is very necessary in advising this treatment under all circumstances; but for those patients who are in a suitable physical condition, amid proper surroundings, and in competent hands, immediate operation will always remain the proper choice.

Clinical Department.

LYMPHATIC LEUKAEMIA IN ACUTE INFECTION, AFTER REMOVAL OF THE SPLEEN.

BY JAMES MARSH JACKSON, M.D., BOSTON.

AND

WILLIAM DAVID SMITH, M.D., BOSTON.

A young man, a college student of twenty-one years, American.

F. H. Not remarkable.

P. H. Enlarged cervical glands removed in childhood. Typhoid fever in 1907. Splenectomy in Switzerland in 1909 following rupture of the spleen in a coasting accident. Blood examination made in Switzerland a few weeks after splenectomy showed essentially a normal blood picture, i.e.:

Red count.....	4,600,000
White count.....	7,800
Hgb.....	68 to 70%
Polynuclear neutrophils.....	58%
Small lymphocytes.....	22.5%
Large lymphocytes.....	2.5%
Transitional cells.....	10%
Eosinophiles.....	6%
Mast cells.....	1%

P. I. May 31, 1913, patient seen complaining of fatigue, moderate headache, sore-throat and slight stiffness of the neck. Tonsils moderately swollen and together with entire pharynx were dry and reddened, but without membrane or exudate. Glands at angle of jaw on right were slightly enlarged, hard, discrete and a little tender.

Temperature 99.4. Pulse 78.

June 2, condition unchanged except that glands on right were decidedly larger and there was discomfort on swallowing.

Temperature 100. Pulse 70.

June 3, condition worse. Tonsils swollen, especially the right, which approached median line. Glands on right side of neck now crowded together into a hard mass almost level with jaw but without fluctuation or evidence of softening. On the left side of neck were several discrete enlarged glands, size of chestnuts.

Temperature 101.6. Pulse 72.

Up to this time the case had been considered an acute tonsillar infection with secondary involvement of the glands of neck. A white count and smear done at this time gave the following result:

White count.....	40,000
Polynuclear neutrophils.....	5%
Lymphocytes, large.....	59%
Lymphocytes, small.....	36%
Mast cells.....	0%
Eosinophiles.....	0%

A stained smear submitted to an eminent pathologist in Boston was reported as follows:

"The smears of blood submitted to me today show appearances which I regard as those of beginning lymphatic leukaemia. The presence of some very atypical basophilic mononuclear cells makes me very suspicious that the case is one of so-called 'acute lymphatic leukaemia'."

June 4, not much change in neck glands; inguinal glands on both sides enlarged to size of beans; axillary and epitrochlear glands also slightly enlarged.

Temperature 101. Pulse 72.

June 5, patient seen in consultation by a well-known Boston internist who confirmed the findings and also demonstrated a small area of relative dullness in the right back in region of root of lung. He considered the case a probable lymphatic leukaemia but suggested the possibility of an absent spleen modifying the blood picture.

June 6, decided improvement in all symptoms, throat less sore, size of glands in neck definitely diminishing, temperature 99.2, pulse 68.

June 8, patient up and about, continued improvement; neck glands palpable but small.

Blood examination—

Red count.....	5,400,000
White count.....	32,600
Hgb.....	90—95%
Polynuclear leucocytes.....	13%
Lymphocytes, large.....	70%
Lymphocytes, small.....	17%
Mast cells.....	less than 1/2%
Eosinophiles.....	0%

June 19, apparently well and leading a normal life.

White count.....	17,000
Polynuclear neutrophils.....	16%
Lymphocytes, large.....	70%
Lymphocytes, small.....	13%
Mast cells.....	1%
Eosinophiles.....	0%

July 14, apparently perfectly well; no palpable glands; white count 10,800.

Aug. 23, 1913.

White count.....	7,000
Polynuclear neutrophils.....	33%
Lymphocytes, large.....	43%
Lymphocytes, small.....	21%
Mast cells.....	1/2%
Eosinophiles.....	2.5%

*April 15, 1914.

No leucocytosis. Red cells normal. Platelets much increased in number.

Polynuclear neutrophils.....	75%
Lymphocytes, large.....	6%
Lymphocytes, small.....	13%
Eosinophiles.....	6%

SUMMARY.

A young man a few weeks after removal of spleen in 1909 showed an essentially normal blood picture.

In 1913, he developed what seemed clinically an acute tonsillar infection; this was quickly followed by marked enlargement of glands of neck and moderate general glandular enlargement involving axillary, inguinal and epitrochlear glands.

This situation was accompanied by a blood picture so typically that of lymphatic leukaemia that no other diagnosis seemed possible.

After a week of sore-throat, general malaise and moderate elevation of temperature the symptoms abated and a normal convalescence as from an acute infection ensued.

Blood examinations done from time to time showed a gradual diminution in the white count and a change in the blood picture from that of a typical lymphatic leukaemia on June 3, 1913, to an approximately normal picture on Aug. 23, 1913 and a normal picture on April 15, 1914.

* This examination was made by Dr. Willard S. Parker.

SUB-MUCOUS RESECTION AS A MEANS OF OBLITERATING SUPERFICIAL BLOOD VESSELS.

BY JOSEPH PRENN, M.D., BOSTON.

IN the *Laryngoscope* of October, 1914, Dr. John A. Thompson, in his article "Uncommon Case of Nasal Hemorrhage," remarks that "the unusual feature was the method of cure by sub-mucous resection."

In the summer of 1914, at the out-patient department of the Boston City Hospital, a sub-mucous resection was done with the same object in view,—that of curing a nasal hemorrhage. The theory upon which this operation was based was, that after taking out the cartilage of the septum a new circulation for the fibrous tissue formation of the septum would have to be established. The endothelial cells of the existing capillaries would have to multiply to form new blood vessels and the current directed inward. The mucosa then will get the amount of blood supply needed for its existence, but not too much to squander. (The increase of the flow of blood to one part of the body, while at the same time diminishing it in another part of the body, goes on in the human economy physiologically as, for instance, during the process of digestion). The result justified the theory.

The patient in question was plethoric. The mucous membrane of the septum was congested. Superficial blood vessels and many bleeding points were present. He also had a vomerian ridge on the bleeding side, not wholly obstructive, but undoubtedly increasing the congestion.

Bleeding during the operation was rather more than usual. (No novocaine with suprarenalin infiltration was used). When the patient was examined at the end of a few weeks the septum was straight, the congestion of the mucosa was all gone, and no bleeding points or superficial blood vessels were to be seen over the operated area. Whether it is advisable to operate during the congested stage, or to wait until the congestion is over, depends upon the case. This case is reported by courtesy of the throat department, Boston City Hospital.

Another case was that of a patient coming to the office with the usual history of frequent nasal catarrh, nasal obstruction, dryness of throat, occasional nose bleed. The tip of the nose was red for the last two years, and the patient, a boy of twenty-one, of good habits, wanted to know whether the latter could be helped.

Examination showed sub-acute rhinitis, mucopurulent discharge along the floor of the nose, not pointing to any of the sinuses. The mucous membrane over the cartilaginous part of the septum showed radiating blood vessels on one side, slight anterior deviation with basal spurs on either side, bathed in pus, touching the

inferior turbinates, and would not admit a probe. Local application of protargol was used and alkaline spray was prescribed. Operation was advised in about a week, believing that it would also do away with the congestion of the tip. The latter belief was based upon the following consideration. The redness of the lobule of the nose, when brought about by inflammatory conditions of the nasal mucosa (and that is usually the case), is due to the existing anastomosis between the blood vessels and the plexus of the skin of the tip of the nose. It stands to reason then, that should we cut the anastomosis at the mucocutaneous junction, further congestion would be stopped, and if we will allow the cut to heal by "second intention," more blood will be necessary to granulate the surface, and the congestion ought to be entirely relieved. That is apparently what happened in this case. The redness of the tip disappeared the second day after the operation, and remained so. No superficial blood vessels of the mucosa are to be seen. The septum is straight.

In order to cut the anastomosis at all points, two incisions about a half an inch in length, at about right angles to the classical vertical incision were made, one at the floor, and the other at the roof of the nose so that they formed a flap. The flap was not sutured, but simply put in place to prevent healing by "first intention."

N.B. The difference between "first" and "second intention" as used in this article is not as marked as in other parts of surgery, for in either case, we are dealing here with linear incisions.

Medical Progress.

PROGRESS IN TUBERCULOSIS.

BY JOHN B. HAWES, 2D, M.D., BOSTON,

Assistant Visiting Physician, Director Tuberculosis Clinic, Massachusetts General Hospital,

AND

P. CHALLIS BARTLETT, M.D., BOSTON,

Assistant, Tuberculosis Clinic, Massachusetts General Hospital.

THE literature on tuberculosis is so enormous, and the work that has been done during the last few years covers such an immense field, that a review of this subject must perforce confine itself to the barest summary of the most striking features. It should also be remembered that there is sure to be a wide difference of opinion as to what are the more important articles and points which deserve comment. We therefore state in the beginning that in this review special attention will be paid to the clinical and practical side of this subject and to those features which we believe will be of help to the medical profession as a whole and not merely to one small group.

Diagnosis. Progress in the early diagnosis of pulmonary tuberculosis or in the diagnosis of early pulmonary tuberculosis seems to have been steady though slow during the past few years. In the field of tuberculosis in infancy and childhood, especially in the recognition of bronchial gland tuberculosis, much work has been done and distinct progress made. Of great importance in this regard is the fact that the difference between tuberculous *infection* and tuberculous *disease* is more clearly recognized. Attention has been called to this by Pritchard,¹ Hawes,² and Bailey.³ In bronchial gland tuberculosis the x-ray has its greatest field of usefulness. Crookshank⁴ strongly urges that "the general practitioner should be encouraged to recognize early enlargement of the tracheo-bronchial glands with no lesser zest than would apply to the diagnosis of the secondary symptoms of syphilis." "It is certain that as many children suffer at one time or another from lodgment of tubercle bacilli in this or that group of glands as from measles or from chickenpox." "The care of the child is the root of the problem in dealing with tuberculosis." In diagnosing bronchial gland tuberculosis the value of "d'Espine's sign" as evidence of enlarged, *but not necessarily tuberculous glands* has been wisely emphasized by many. Likewise, in X-ray work, it has been shown that enlarged glands at the lung roots may be due to many other infections aside from tuberculous. These are most important points.

Lucas⁵ presents good diagrams showing the relation of bronchial glands to the bronchi and urges further study of this form of tuberculosis. Treatment of these early cases of infection brings excellent results; if there is a delay until more striking evidence of disease is present, the chances of recovery are too often gone. Lucas gives a most instructive symptom-complex of tuberculosis in children which should be read by every physician. It is of interest to compare this with a similar symptom-complex published in the 1913 report of the Massachusetts Tuberculosis Commission.

In adult disease, the X-ray workers are as enthusiastic as ever, declaring that by means of the X-ray lesions can be discovered in the lungs long before they can be recognized by clinical investigation. These are the words of enthusiasts however. The majority of the profession whose opinion is of value in this line, take the more conservative view that while the X-ray is a useful adjunct and should be made a part of a routine clinical investigation, it should never replace clinical methods. Moore⁶ states that "the gross lesions of pulmonary tuberculosis give characteristic appearances on the radiograph," but that in "the border-line cases the Roentgen ray cannot determine the activity of a tuberculous process."

Claypole⁷ describes human streptotrichosis as a cause of error in diagnosis and is of the opinion that it is commoner than is supposed to be the case. Lee⁸ presents in detail several cases of

this type. Davis⁹ describes the lesions of nocardia and states that they "clinically are not ordinarily distinguished from pulmonary tuberculosis." L. Brown¹⁰ in a most interesting paper discusses errors in diagnosis of pulmonary tuberculosis. Among other conditions which may be mistaken for tuberculosis he describes cases of Hodgkin's disease, malignant tumors, syphilis and cardiac disease.

Ewart¹¹ describes "Perez' sign"—motor joint crackles—as a possible source of confusion in diagnosis. Hawes¹² has confirmed this point on a large number of patients and has taken up as well the part played by muscle sounds, tendon or bursal sounds, and atelectasis in addition to motor joint crackles. He concludes that only muscle sounds and motor joint crackles are real sources of error, and urges that in all doubtful cases the patient be made "to go through the motions of breathing" without taking any air into the lungs through mouth or nose, in order to decide whether the sounds heard are râles or are due to extraneous causes.

In regard to specific diagnosis, much work has been done but little real progress made. In children 5 years old or under, a positive skin tuberculin reaction is recognized to be of the greatest value as pointing to a tuberculous infection; in adults, only a positive subcutaneous tuberculin test performed by experts with a *local* as well as a *general* reaction is of value. Fildes,¹³ Radcliffe, and McIntosh, Pringsheim¹⁴ and others, have discussed this subject at length.

The various concentration methods of sputum examination by anti-formin and in other ways, have a definite place in sanatoria and other institutions. As a means of diagnosis for the general practitioner, there are hardly available.

On the whole, the medical profession seems to be slowly but surely learning that it is not by any specific tuberculin reaction, X-ray, etc., but by a careful and painstaking study of the patient's history, occupation, habits, constitutional and local signs and symptoms, that the diagnosis of early pulmonary tuberculosis can be made.

Prognosis.—Progress in estimating the patient's chances in the future has consisted chiefly in relegating to their proper places various tests which at first were thought to be of great value in prognosis. The study of the leucocytes, according to Arneth¹⁵ with the shifting of the nuclear picture to the left or the right attracted undue attention. While in certain cases it gives valuable evidence, the technique is far too difficult, the process too long, and the chances of individual error too great to make it a factor of any importance in prognosis. Likewise with regard to the diazo and urochromagen reactions, final results have not shown these tests to be of real help. On the other hand it seems to be accepted that a gradual decrease in the number of bacilli in the sputum with particular reference to the appearance of degenerative forms, etc., is of some value providing, of course, that the work is done by one qualified to judge. Kirchen-

stein¹⁶ from Spengler's private laboratory at Davos writes interestingly on this subject. Brown¹⁷ in a paper entitled, "When is a tuberculous patient cured?" concludes with the following sentences which merit grave consideration: "In conclusion, as a confession of faith, I may say that I believe that pulmonary tuberculosis is curable; that spontaneous healing of tuberculous infection occurs frequently, that healing of clinical tuberculosis may, but rarely does, occur; that permanent arrest is the most frequent termination of the disease in those who are later able to follow their usual occupations; that temporary arrest of longer or shorter duration occurs in all except the acute cases; and that continually progressive disease follows only upon several temporary arrests."

This is a sound and sane summary of "prognosis" in pulmonary tuberculosis. Fishberg¹⁸ and others, however, have written in the more optimistic view calling attention to the fact that while the frequency of tuberculosis is not decreasing, its power to kill is slowly but steadily diminishing.

Treatment.—A consideration of progress in the treatment of pulmonary and non-pulmonary tuberculosis may naturally be divided as follows:

1. Is sanatorium treatment worth while?
2. Artificial pneumothorax and its value.
3. Tuberculin and its value in treatment.
4. Sunlight treatment—heliotherapy.

Is sanatorium treatment worth while?

Much has been written pro and con on this subject. Wilkinson¹⁹ of England is the strongest upholder of the negative. He believes so firmly in the curative power of tuberculin that he sees no possible use in sanatorium or any other form of treatment except that of tuberculin. His theories are yet to be proved, however. The great majority of writers, while of the opinion that much can be done to promote the efficiency of sanatorium treatment, and that it is still far from perfect, still believe that it offers the greatest opportunity for the cure or arrest of the disease that we have at our disposal. Bailey²⁰ and MacCorison describe a scheme for promoting the efficiency of sanatoria by dividing patients into a "sanatorium" and a "hospital" class. In the former are placed all those patients who are really trying to get well and who cooperate with their physicians. To the latter class belong those who merely regard the sanatorium as a first-class boarding house. That this system is capable of bringing about excellent results has been clearly demonstrated in Massachusetts Sanatoria. Hawes²¹ describes what is done in Massachusetts to keep the patient well after leaving the sanatorium, and the methods whereby cooperation of local forces, public and private, may be obtained. Bolduan²² of New York, in a distinctly pessimistic view, speaks of the futility of taking patients out of bad surroundings to send them to a sanatorium and then

allowing them to return to the same bad conditions at home. Goldstein,²³ writing also from the New York point of view, urges that special factories or other specially conducted places of employment be created for giving suitable employment to post-sanatorium cases. Numberless other papers have been written on this subject. The general feeling seems to be that the sanatorium is worth while; that it does play a large part in our tuberculosis campaign, but that to make it occupy the place it really should hold, the treatment of the patient should begin long before he enters and long after he leaves the institution. This, as Pottenger²⁴ clearly points out, means the prevention, detection, and treatment of tuberculous infection in childhood and the supervision of the consumptive after leaving the sanatorium.

Artificial Pneumothorax and Its Value. The medical profession seems to have reached a saner point of view in regard to the value of this method of treatment than was the case a year ago. Saugman²⁵ states as his impression after seven years' treatment of over 200 cases, that during the first six months this treatment should be carried on only in a sanatorium or hospital and that "only in exceptional instances should pneumothorax be used on patients in their homes." Balboni²⁶ states that "the patient ought to follow sanatorium régime treatment at the same time." Unfortunately, few if any of his patients were actually in a sanatorium while under treatment, but were living at home, many of them in the crowded parts of the city. Balboni further states that "the patient should be fully informed that the treatment is long, tedious troublesome, and expensive, and not devoid of dangers." Lyon²⁷ describes results as obtained at the Rutland State Sanatorium in Massachusetts. Floyd²⁸ of Boston describes the class of cases suitable for this treatment. The general feeling is that this treatment in skilled hands, under careful supervision in a sanatorium or hospital, may do a great deal of good in a small group of selected cases who do not respond to other methods of treatment.

Tuberculin and Its Value in Treatment. As stated above, Wilkinson²⁹ of England is the foremost in the ranks of those who believe tuberculin will cure all forms of pulmonary tuberculosis. His claims are so extravagant, however, as to lose nearly all value. Bennett,³⁰ in a most useful little book urges great conservatism in the use of tuberculin in pulmonary disease. The opinion of the majority of those able to judge is that tuberculin, like artificial pneumothorax, may do good in selected cases, particularly those without fever, and who have reached a stationary condition; but that it should only be given by those skilled in its use and when the patient is under constant medical supervision. No comment is needed on the Friedman episode, which is now a thing of the past.

Sunlight Treatment or Heliotherapy.—That direct sunlight has a remarkably beneficial effect

on all forms of tuberculosis is a fact that has not been sufficiently impressed on the minds of the medical profession. The work of Rollier³¹ in Leysin, France, which had not attracted attention until very recently, is now a subject of almost universal comment and discussion. During the past year, not only Dr. Rollier's own description of his work, but the articles by Hinsdale³² and others have made the profession realize the importance of this hitherto neglected method of treatment. Patients are exposed to direct sunlight little by little, first beginning with the feet below the knees, for five minutes five times a day, and then increasing so that finally the entire body is bare for several hours at a time. This process of gradually exposing the skin to the sun must be carried on with care or else bad effects may follow. The results on the local process as well as on the patient's general condition are remarkable; were it not for actual photographs, they would scarcely be believed. Such treatment in modified form is now being carried on in this country, especially at Buffalo, New York, and at the Westfield State Sanatorium in Massachusetts. Heliotherapy is such a cheap form of treatment and under anything like adequate supervision is capable of bringing about such good results that its use is bound to become far more widespread. It would be an excellent thing if every physician were to read either Rollier's original papers or Hinsdale's description of Rollier's work.

Bovine Tuberculosis. The importance of the campaign for clean milk in the prevention of various forms of tuberculosis is becoming more and more recognized. Mitchell³³ states that "cows' milk containing bovine tubercle bacilli is clearly the cause of 90% of the cases of tuberculous cervical glands in infants and children." He refers particularly to the district around Edinburgh where tuberculosis in cattle seems to be particularly common. Although German observers do not confirm Mitchell's or Fraser's³⁴ figures, placing the percentage of bovine infection so very high, yet they agree that bovine tuberculosis is a much more important factor than was formerly considered to be the case. The teeth and faucial tonsils are the most important channels of infection in these cases.

Laryngeal Tuberculosis. Much has been written on laryngeal tuberculosis and its treatment. The general feeling in this country that this was secondary to a pulmonary process, and that its progress toward healing depended almost entirely on that of the patient himself, led to a somewhat over conservative attitude toward this condition and a tendency to let it entirely alone, except for mild palliative measures. At present this feeling seems to be changing somewhat and a tendency toward more radical measures to be taking its place. St. Clair Thompson³⁵ takes the conservative standpoint that "sanatorium treatment is at present the first and most valuable method we have for arresting laryngeal tuberculosis," and that "local measures are much more

promising under sanatorium treatment." This point of view, which places sanatorium treatment first, but which does not do away with local treatment, radically operative or otherwise, seems eminently sane and sound.

Non-Pulmonary or "Surgical" Tuberculosis. Of all forms of non-pulmonary tuberculosis, that of the cervical glands and of the genito-urinary tract has received the most attention. There has been a marked change in the attitude of most surgeons as to the treatment of tuberculous cervical adenitis. While there are still a few, notably Dowd³⁶ of New York, Fraser of Philadelphia, Ladd³⁷ of Boston, and others, who still claim that the so-called "radical operation for the removal of tuberculous cervical glands" is the best and safest course in all cases, the vast majority of the medical profession are now apt to look upon an operation in those cases "as an incident great or small as the case may be, in a course of treatment the most important part of which comes before and after operation." Hastings³⁸ of New York, Rollier³⁹ of France, Chadwick,⁴⁰ Hawes,⁴¹ and numberless others, have clearly demonstrated that in most cases of tuberculous cervical adenitis, by the removal of diseased tonsils and the cleaning up or removal of decayed teeth, and by proper hygienic constitutional treatment with food, fresh air, heliotherapy, tuberculin, and other measures, an operation is sometimes rendered absolutely unnecessary, and often reduced to some simple measure, such as opening and draining a small abscess cavity. In many cases, as shown by Hastings and Hawes, tuberculin alone seems to cause the glands to disappear, while the results obtained by Rollier and those who have tried this method of treatment show how unnecessary and useless the radical operation may be.

Genito-Urinary Tuberculosis. In genito-urinary tuberculosis, Barney⁴² has done a valuable piece of work in calling attention to the seriousness of tuberculous epididymitis and by showing in how large a percentage of cases even under excellent treatment this condition is followed by generalized tuberculosis of the genito-urinary tract. O'Neil⁴³ and Hawes have urged the use of hygienic measures and of tuberculin in all forms of tuberculosis of this region, before, after, and sometimes in place of, operative treatment.

Economic and Social Aspects of the Tuberculosis Problems. Progress in this direction has been along lines laid down sometime in the past. Chief among studies in the economic and social aspects of this disease are those which call attention to the dangers of open cases of tuberculosis and the need of preventing this source of infection if progress is to be made. Lampson⁴⁴ presents an interesting study of the spread of tuberculosis in tuberculous families showing that "67% of the individuals of these families (in which there was an open case of tuberculosis) excluding the centre cases, show evidence of tuberculous infection." The fact that his chief criterion of tuberculous infection was the von

Pirquet skin reaction, tends to detract from the force of his statement. MacCorison and Burns⁴⁵ of the North Reading State Sanatorium in Massachusetts, in similar fashion, have made a careful study of a large number of the families from which their patients came, with equally striking results. Their positive cases were ones of clinical tuberculosis, however, and not those with a positive skin tuberculin reaction only. Hawes⁴⁶ has carried this work still further and has shown the immense amount of good that can be done by following up patients discharged from sanatoria and by introducing a system whereby such patients can be kept under proper supervision and the members of their families examined.

CONCLUSION.

In conclusion it seems to us that in the diagnosis of adult tuberculosis, progress has been made not along any one line, such as the x-ray, tuberculin, etc., but by a realization that careful and detailed study of the patient, his history, constitutional signs and symptoms, as well as his lungs, will enable us to make an early diagnosis of this disease.

Bronchial gland tuberculosis in childhood, and its diagnosis with a clear conception of the symptom-complex of childhood tuberculosis, is a subject the importance of which cannot be overestimated. The increasing interest in condition by the medical profession is alone a distinct step in advance.

In treatment, the use of sunlight in all forms of tuberculosis is the great step forwards. Artificial pneumothorax has assumed its true position as an agent of value in a certain small group of cases; tuberculin is looked upon more conservatively in pulmonary disease and as an agent of great value in non-pulmonary tuberculosis.

From the economic and social side it is gratifying to note that childhood infection and its prevention and also the supervision of the consumptive *before* and *after* he goes to a sanatorium have been given the important consideration that they deserve.

Reports of Societies.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

MEETING OF WEDNESDAY, NOV. 25, 1914, AT 8.30 P.M.
THE PRESIDENT, DR. WILLIAM DUFFIELD ROBINSON,
IN THE CHAIR.

SYMPOSIUM: THE PREVENTION OF DEFORMITIES.

SCHOOL LIFE AND THE ONSET OF DEFORMITIES.

DR. WALTER S. CORNELL, Director Division of Medical Inspection of Public Schools: An article appearing in a recent issue of *The Weekly Roster* called attention to the importance of orthopedic defects from a standpoint not usually considered by the physician. The broad viewpoint outlined we would do well as physicians to consider: "Deformity is to be seen everywhere. Its presence is deplorable as it tells in very loud words of the physical and emotional suffering of the afflicted and the terrible handicap they are doomed to carry through life. It is indeed to be deplored that the persons so afflicted in very large proportion could be, but were not,

treated in early life so as to have been cured or very greatly improved. The distress and resentment of many entering adult life, when they contemplate what might have been done for them, is not pleasant to consider."

Deformities considered in connection with school life are almost entirely those of the spine, comprising principally stoop shoulders and lateral curvature. We need only to mention the intimate relation of a contracted chest to tuberculosis, general malnutrition and the prevalence of lateral curvature to appreciate the major relative importance of these two physical defects to the entire remaining field of orthopedics. It is the consideration of physical defects in their association with others that forms the most basic principle of medicine in the study of growing children. Stoop shoulders and flat chest are in this paper considered as one condition. The causes of stoop shoulders are many. Workers in tuberculosis hospitals first noted the close association of pulmonary tuberculosis with the condition and provided nose and throat dispensaries that fresh air might be obtained by these patients through their noses as well as through house windows. The causal relation of low nerve tone and malnutrition, of defective eye-sight and hearing, and of low neuro-muscular tone has also been recognized. Most cases of lateral curvature are primary in causation and due to fatigue of the back muscles from over-long school periods. Our school curriculum should be amended to provide frequent periods of bodily freedom and relief. It will be remembered that "Ben Hur" asked to row alternately on the starboard and port sides of the galley, upon noticing the one-sided development of his fellow galley slaves. The routine medical inspection of children will prevent a certain proportion of the stoop shoulders and scoliosis by the correction of myopia and astigmatism, removal of nasal obstruction and treatment of catarrhal deafness. The great attack must be made from the standpoint of personal hygiene, the standpoint of direct corrective exercises. The system of corrective exercises just introduced into the Philadelphia schools is under the direction of the Department of Physical Education, which coöperates with the Department of School Medical Inspection. Special exercises are given these children in the schools and to be performed at home. I would make an earnest plea for the greater emphasis by orthopedists upon the common defects rather than upon new operations for serious and crippling deformities; a plea to the medical profession for the recognition of the symptom complexes in developing children; a plea for the medical care of patients upon the basis of hygienic living, with the courage to charge for advice which prevents disease; a plea for the better understanding of the intimate relationship of defects of the teeth to defects of the nose and throat; and finally, a plea for the recognition by medical colleges of the necessity of instruction to students upon the diseases and defects of children of school age.

TUBERCULOSIS IN RELATION TO DEFORMITIES AND THEIR PREVENTION.

DR. HENRY LING TAYLOR, New York City: Tuberculosis of the bones and joints is one of the commonest causes of crippling deformities which are a grave personal handicap and a serious economic loss to the community. In order to prevent the annual increase in the number of incapables

from this source, we must first direct our preventive measures against the dissemination of tuberculosis:—

1. By official inspection of herds and milk products, with the view of stamping out bovine tuberculosis and preventing the distribution of contaminated dairy products.

2. By segregation of the distribution of human tubercle bacilli and the disinfection of their sputa.

3. By the invigoration of children and youths and adults through a more hygienic life.

When a tuberculous joint is present we must make an early and accurate diagnosis and institute effectual treatment as early as possible, continuing it until the disease is quiescent. During this time the joint must be fixed in its most useful position so that when the disease is arrested the limb may still be serviceable, even if joint motion is diminished or absent. Severe terminal deformities of the limb may be corrected nearly always by safe and comparatively simple surgical operations and should be so corrected much oftener than they are. Without having exact figures, I do not think joint tuberculosis is quite as common in New York, and probably in other large towns in this region as formerly. We do not see so many severely deformed people on the streets. Whatever difference of opinion there may be about the bovine infection of tuberculosis there is no difference in opinion of the practical results of having children in close companionship with advanced consumptives. Time and time again I have found cases in the clinic in which the child was sleeping in an unventilated room with the father in an advanced stage of tuberculosis and three and four cases of tuberculous infection in the same family. These were not inherited cases, for we have seen the same thing in those of the same household but not related. In one case we found that the nurse of a baby was tuberculous. Failure in early and accurate diagnosis of deformity in bone and joint tuberculosis is as common as it is disastrous. Probably one-half of the fixed deformities are due to mistaken diagnosis or no diagnosis at all. The early diagnosis is not always easy even for specialists. The term "rheumatism" is one which is rapidly passing out of use in scientific language. "Rheumatism" means infection and the source should be ascertained. There should be willingness to examine thoroughly cases which seem to be trivial. The patient should be built up by general hygiene as in pulmonary tuberculosis, and probably a systematic application of sunlight to the naked skin, according to an exact and simple technique, is the most important advance in the last ten years in the treatment of surgical tuberculosis. In our fresh air home on Long Island we have just finished our eighth year and the average gain in children kept out in the open air has been seven pounds per summer per child for seven years. In the last year we have used direct sunlight treatment, putting the children in the sunlight for six hours a day without a stitch on them and the results have justified the belief that this treatment is probably the most important advance in the treatment of joint tuberculosis in the last ten years. In the local treatment of tuberculous joints, with fixation properly applied, you will have little need of traction. The limitation of activity is extremely important. If the simple principle is observed of fixing the joint in the most useful posture more than half of the bad deformities will be prevented. We operate freely in adults and sparingly in children.

THE STATUS OF THE GENERAL PRACTITIONER IN THE
PREVENTION AND CORRECTION OF DEFORMITIES.

DR. H. AUGUSTUS WILSON: Your committee has deemed it desirable to consider the status of the general practitioner in the prevention and correction of deformity. The orthopedic surgeon, being often the court of last resort in cases of progressive bodily deformity, is in a position to review all of the past history of the patient. One constantly hears that the family physician has given assurance that the child would outgrow its bow-legs; that the early pain of tuberculous bone disease was growing pains; that non-tuberculous processes were rheumatism; that normal feet of children required arch supports. The general practitioner in the country differs widely from the general practitioner in the city. The former is compelled, and the latter elects, to prescribe for all conditions. In city life there appear to be three types of the general practitioner: (1) The self-contained physician who elects to be the medical autocrat; (2) the distributor to specialists; (3) the coöperator. The self-contained autocrat attempts to emulate the country doctor without the necessity of so doing. The increasing specialization has become a necessity, because of the disasters often caused by the self-contained autocrat. The distributing general practitioner is usually a skilful diagnostician with insufficient confidence in his own knowledge of therapeutic measures. He selects a specialist to whom the patient is sent with instructions to remain under his care for the specific lesion. It is difficult to determine the divided condition of the patient affected with three or more so-called special diseases, as seen in the case of a young girl of sixteen who within a period of four months was elaborately studied by ten different specialists. The co-operating general practitioner is the highest type of all, for he combines the best and avoids the worst features of the others. It has been my experience that the best ultimate results have been obtained when I remained in coöperation with the general practitioner. In the great majority of conditions ultimately becoming orthopedic problems, the onset and early progress are so inconspicuous that in the beginning they defy accurate diagnosis. It would seem that the general practitioner has the largest opportunity to determine the relative importance of the various etiological factors in scoliosis in school children. In the early history of bone tuberculosis there is a period of uncertainty when the symptoms are attributed to other causes. The referred pains are usually classed as "rheumatism," a word which should be stricken from our vocabulary. The etiological importance of the eruptive fevers in the producing of joint affections; of typhoid fever in post-typhoid dislocations; of often remote gonorrhea in subsequent arthritis; of various factors in numerous forms of backache; and of pyorrhea in a vast variety of non-tuberculous joint affections, as well as the expedience of employing passive motion in treatment, is a problem worthy of close attention. The general practitioner has a most difficult task when he encounters congenital deformities. Whether he knows it or not, he is confronted with Wolf's law that all prolonged alteration of the function of any part of the body, either congenital or acquired, is surely followed by anatomical changes. He must analyze carefully the many conflicting statements regarding the advisability of immediate correction or of postponement. After all the various problem-students have made their re-

ports, it is often the province of the family physician to decide, for the family, upon the actual diagnosis and to direct the treatment. The various laboratory aids to diagnosis, when combined with an analysis of clinical findings, often materially assist in diagnosis. With the essential clinical phenomena as a basis, doubt can often be changed to certainty by the employment of radiography, blood tests, urinary analyses, and bacteriological research, but I know of nothing more confusing than a radiogram, unless it be the report of a radiographer who attempts to make a diagnosis without accurate clinical data. I believe there is entirely too much hastily conceived and misapplied treatment. The essential ingredient of any therapeutic measure should be skilful diagnosis. This is accomplished only by devoting time and discernment to a skilful weighing of all obtainable facts.

DISCUSSION.

DR. R. TAIT MCKENZIE: To the various factors bearing upon deformities I would add, the design of clothing, and the construction of furniture. I shall confine my remarks, however, to the subject of postural deformities that are non-tubercular. As soon as we assume the upright position the pressure of the whole body weight coming upon the feet gives a tendency to their eversion, thus threatening deformity of the arch. The next point at which the bony structure may yield is at the knee, and from the slightly bowed leg there may be the condition of knock-knee. With an exaggeration of the curve which may occur at the lower part of the back there is a compensating curve in the upper part of the back. The ribs are carried downward, the chest is flattened and the abdomen protrudes, giving the typical condition of bad posture with the consequent disarrangement of the contents of the upper zone of the abdomen and the long train of symptoms familiar to all. Many faulty positions are acquired in the school room where the child has to sit still for long periods of time. City conditions are also at fault, for the child has not the opportunity for play which gives the best development. This, however, is being corrected by the establishment of playgrounds. Occupation is another factor in etiology. In many occupations we are unable properly to use our muscular system. It is not surprising that we find motormen and hospital nurses flat-footed. The underlying principle in all these deformities is fatigue in some form. Much can be done in the schoolroom by breaking up the long periods of study by short periods of rest and exercise, and by tests in posture. It has been found that one of the chief causes of the stooping of children has been in the structure of the clothing by which a constant pressure is felt on the back of the neck. This is remedied by changing the cut of the garment.

DR. JAMES K. YOUNG: Three sources of infection in tubercular children are (1) cows' milk; (2) nurses and attendants; (3) infected rooms. The faucial tonsils seem to be the chief channels of infection. My clinical observation leads me to believe that suppuration does not so frequently occur in these instances of bovine infection as in the human. The importance of the source of infection being that of nurses and attendants has so impressed Mr. Thomas A. Edison that he has personally supervised a photo-play entitled the "Temple of Moloch," which has for its climax the discovery of the infection of two children by a tubercular nursemaid.

The photo-play is to be used by the Tuberculosis Commission in its warfare against the white plague.

The occupations which seem to be most suitable are not always the best adapted to or selected by the deformed person. Music, especially orchestral, wireless telegraphy and the telephone have afforded valuable means of livelihood. School teaching is a suitable occupation for those in whom the tubercular process has been arrested.

DR. CORNELL, closing: I have learned much to-night and shall urge upon our school authorities the importance of vocational training of crippled children and of the provision of ample sunlight in our school buildings. The psychology of crippling deformity is an aspect of the problem totally different from that of the mechanical treatment and claims our best endeavor. I would especially plead for treatment by the medical profession of crippling deformities from the preventive standpoint.

DR. TAYLOR, closing: The other papers have brought out much of importance and of practical suggestion. It is gratifying to know of the advance in postural work outlined by Dr. McKenzie. The subject of occupations for cripples I am especially interested in. I would not be misunderstood regarding the value of the x-ray. What I said was that in the early cases the x-ray frequently showed nothing. I do not wish to be understood as believing that you cannot get good results by traction, but, as I have said, if you will handle your case with fixation, properly applied, you will have little need of traction, and a little motion is worse than a stiff joint.

Book Reviews.

Practical Therapeutics. By DANIEL M. HOYT, M.D., formerly Instructor in Therapeutics, University of Pennsylvania, etc. Second edition, revised and rewritten. pp. 426. St. Louis: C. V. Mosby Company. 1914.

This volume includes in its discussion materia medica and prescription writing, together with a description of the most important new and non-official remedies accepted by the Council on Pharmacy and Chemistry of the American Medical Association. This second edition has been revised, as is peculiarly necessary in dealing with the general subject of drug therapeutics. It has been improved in various ways, as, for example, through the brief description of vaccine therapy, and practical suggestions regarding office dispensing. The subject matter is conveniently arranged under general headings descriptive of the use of various therapeutic agents. Throughout it is eminently practical, clearly written, and admirably arranged for reference. An extensive appendix of upwards of a hundred pages describes new and non-official remedies, which are coming to take an important place in therapeutics. An excellent index of drugs,

which is really much more than an index in the information it gives, concludes this generally satisfactory volume.

Diseases of the Skin, Including the Acute Eruptive Fevers. By FRANK CROZER KNOWLES, M.D., Instructor in Dermatology in the University of Pennsylvania; Clinical Professor of Dermatology, Women's Medical College of Pennsylvania. Octavo, 546 pages, with 199 engravings and 14 plates. Philadelphia and New York: Lea and Febiger. 1914.

This volume adds one more to the many published in recent years, devoted to the convenience of the student and general practitioner of medicine. In it the writer has tried to cover all of the eruptions that come on the skin and the adjacent mucous membranes, and includes the exanthemata. In the domain of therapeutics the author confines his recommendations chiefly to remedies that have been successful in his own hands, a wise resolve in a book addressed solely to students and general practitioners. Syphilis, pellagra, and tropical diseases are dealt with at greater or lesser length. The illustrations are numerous and remarkably good. Dr. Knowles is to be congratulated on producing a praiseworthy book in a field already pretty well occupied by successful predecessors.

A Text-Book of Pathology. With an Introductory Section on Post-Mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By FRANCIS DELAFIELD, M.D., and T. MITCHELL PRUDDEN, M.D. Revised with the coöperation of FRANCIS CARTER WOOD, M.D. Tenth edition. Completely revised. 8vo., 1144 pages, illustrated by 14 full-page plates in black and colors, and by 694 line and half-tone cuts. New York: William Wood and Company. 1914.

This edition is slightly improved over previous editions. It is possible in this, as in any text-book, to point out numerous omissions, some errors and instances of undue emphasis placed upon certain subjects. The text-book has been for many years one of the standards in pathology and it has more than held its own with succeeding editions. This edition is brought thoroughly up to date and considerably improved by an increased number of references and illustrations. The book as a whole is so excellent that it does not seem fair in a short review to call attention to the few minor deficiencies which can be found.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JANUARY 28, 1915.

EDITORS.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*
126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

BIOLOGIC ASPECTS OF EARLY MARRIAGE.

In the July, 1914, issue of the *Journal of Heredity*, the official organ of the American Genetic Association, was published a brief paper by Casper L. Redfield, of Chicago, on the "Results of Early Marriage," raising the question whether it leads to the production of desirable children and offering a reward of \$200 for the reporting of human cases "where rapid breeding led to good results from an intellectual point of view." The reward, which was deposited with the Association in April, 1914, has recently been returned to the donor, no one having produced evidence of the kind required.

In an analysis of a large amount of statistics, Mr. Redfield has been able to find no person of eminence produced among families in which there are more than three generations in a century. In his conclusions from this, he says:—

"If the majority of people are produced by breeding faster than three generations to the century, and yet no very eminent person was ever produced within that range, the conclusion is obvious. In 33 states the legal age of marriages ranges from 15 to 19 years for boys, and from 13 to 17 for girls. In the same states there are many marriages at less than legal age which are considered valid unless objection be made. Such early marriages result in rapid generations, and continuous rapid generations lead to the production of mental and moral defectives."

In short, Mr. Redfield believes that the optimum conditions of human breeding would be reached by the production of the majority of children from parents of an average of not less than 33 1/3 years.

It seems that these conclusions rest on the basis of a possible common fallacy which underlies many eugenic and other arguments,—namely, the mistaking of cause for effect. It is not that early marriages, resulting in rapid generations, lead to the production of mental and moral defectives; but that individuals of the type tending to produce defectives are more likely to marry early, hastily, and unwisely than the more discreet individuals of higher type, who postpone marriage until they can achieve better pecuniary environmental conditions. Such conditions, in turn, often react favorably on the offspring, giving even the weaker children of older parents educational and hygienic advantages which enable them to surpass the physically stronger children of younger but poorer parents. Could similar advantages have surrounded the parents of higher type during an early marriage their output in quantity and quality of desirable children might have been much greater. In other words, it is not late breeding which secures intellectual or other superiority, but the accrued circumstantial advantages of environment which oftener surround late than early marriages.

Even if it be true that there are no persons of intellectual eminence among the offspring of families breeding faster than at the rate of three generations to the century, this does not prove that the breeding of good stock from younger marriages is not desirable. After all, the bulk of the world's work is and always must be done by persons not of intellectual eminence. Such people are needed only in moderate numbers as leaders. What is fully as essential, and what we are in far greater danger of losing, is a rank

and file of humanity made of the most healthy, vigorous physical fibre. Such individuals are most likely to be bred from parents during the decade of greatest reproductive energy, from 20 to 30. Desirable parents marrying at 20 and producing their children during these years would have an average age of 25 at the birth of desirable children, or four generations in a century. That this is not now the case is because of the economic conditions, which do not deter the rash persons of undesirable stock, but do deter the thoughtful individuals of higher type from early marriage.

As a matter of fact, there is here a conflict, as in many other human relations, between two types or ideals of civilization, the racial and the individual. Doubtless the interests and advantages of the individual are best subserved by late marriage, leading to fewer offspring surrounded by a superior environment. This process, as the experience of history has shown, undoubtedly leads to the production of the highest individual types, but unfortunately it ultimately leads to family and race extinction. The racial ideal, on the other hand, aims at the production of the greatest number of individuals of a good type, though not of the highest, with early marriages surrounded by sufficiently good environment to ensure proper development and perpetuation of the type. Such a method inevitably involves sacrifice of individual advantages for the sake of guaranteeing race survival.

Probably the biologic desideratum for any race, or for the human family as a whole, is not slow, late breeding, which is only Malthusianism under another form, but the maintenance of a majority of physically superior individuals bred under good environment from parents during the third decade of life. Gradual improvement of this stock could be effected by encouraging early marriage of desirable parents, which would increase physical race efficiency not only directly, but indirectly by lessening the amount of venereal disease among the higher types. Intellectual leaders are bound always to occur as "sports" under any method of breeding. Of course such discussion is academic rather than practical, since these questions will ultimately be settled not by conscious but by spontaneous evolution. That human type, however, will probably in the long run survive and dominate which by means of early marriage can most effectively combine the racial with the individualistic ideal in civilization.

THE TREATMENT OF RUPTURED TUBAL PREGNANCY.

IN another column of this issue of the JOURNAL we publish a valuable study by Dr. Young, based on an analysis of sixty-two cases of ruptured tubal pregnancy occurring in the gynecologic service of the Boston City Hospital since 1902. The chief and most important conclusion derived by the author from this study is the undesirability of immediate operation in every case, a conclusion in which we most heartily concur with his judgment. Not many years ago it was the teaching of practically all surgical clinicians that every case of ruptured tubal pregnancy should be operated upon at sight, and doubtless many lives have been sacrificed to this well-intended but misplaced surgical zeal. As a matter of fact, it is exceedingly seldom that a patient dies of the first, or even the second hemorrhage following ruptured tubal pregnancy. It is only repeated hemorrhages, or injudicious intervention, which give the *coup de grâce* in most cases; and in not a few, as is well known, nature may even effect a spontaneous cure. The desirable time for operation in tubal rupture is not when the patient reaches the hospital exhausted by her journey and perhaps just at the close of a fresh hemorrhage, but after several hours of rest and warmth in bed, with judicious stimulation, when the operation can be done upon a patient with improving general condition, rather than at the moment of maximum depression. These facts were recognized by Robb in 1908 and their truth is reëxemplified with additional force in the present article by Dr. Young. There are, of course, cases in which immediate operation is desirable in the presence of signs of obviously progressive hemorrhage. These, however, are the desperate few; the majority benefit by a course of more moderate conservatism.

As to the type of operation to be preferred opinions differ. It seems, however, that with a clear diagnosis, the abdominal route is almost invariably to be preferred. Operation from below is an operation in the dark, without positively reliable control of hemorrhage and without opportunity to inspect and cleanse the peritoneal cavity.

In the differential diagnosis of tubal abortion from tubal rupture there are a few signs of value. In tubal abortion (the ovum being lodged near the fimbriated extremity of the tube), there is relatively little or no concomitant uterine

enlargement, the hemorrhage is less profuse and the abdominal symptoms less urgent than in tubal rupture. In tubal rupture not only are the hemorrhage and abdominal distress greater, but, the ovum being lodged nearer the proximal extremity of the tube, there is usually uterine enlargement corresponding with the duration of the pregnancy.

In the present series eight of the fifteen fatal cases are said to have had shock as a cause of death. Doubtless in some of these the shock was due primarily to injudiciously precipitate operation at a time of minimum resistance immediately after a hemorrhage. In some, however, it is probable that life might have been saved by the employment of transfusion, a procedure which has been applied to only a few of this series of cases. We cannot agree with Dr. Young in his attitude towards transfusion. Given a judicious selection of the time for operation, the recovery or death of a patient with ruptured tubal pregnancy will depend upon the amount of blood lost, the operative shock being in itself small and approximately the same in all cases. Where the hemorrhage has been so great as to portend death, a transfusion promptly done, under the anesthesia of the original operation, as soon as the source of bleeding has been controlled, will generally turn the scale, and, by replacing a considerable part of the blood lost, makes it possible for the patient to live. Salt solution, which merely replaces the volume of the circulation, is no adequate substitute for whole blood. It would seem that ruptured tubal pregnancy is preëminently a condition in which the beneficent procedure of transfusion is a most valuable life-saving measure. It is by no means indicated as a routine procedure, but when employed in critical, borderline, or even moderately exsanguinated cases, tends to expedite convalescence, and to lessen shock and liability to sepsis, even if it does not actually save a patient who otherwise would have died.

With judiciously conservative selection of the time for operation, with the employment of the abdominal route, and with the performance of transfusion in all cases of whose recovery any reasonable doubt is entertained, the mortality of ruptured tubal pregnancy should be diminished to an irreducible minimum.

NEW YORK'S NEW SANITARY CODE.

For some time past it has been felt by the New York City health department that a new sanitary code should be enacted, for, as Commissioner Goldwater expresses it, the code which has been in force for many years has been patched and padded from time to time, until it lacked continuity, coherence and clearness. Accordingly, an entirely new code has been adopted by the board of health, and this, while re-embodiment the provisions of the old in simplified terms and in more logical arrangement, includes twenty new sections which are in large measure the result of recent observations and investigation, and which, it is believed, will effect a wider application of the principles of sanitation.

It has been asserted more than once that important legislative powers have been unwarrantedly seized by the small group of officials constituting the board of health, but Dr. Goldwater explains that these powers, and the responsibilities attending them, have not been seized at all, but, on the contrary, have been thrust upon the board by law, and been most reluctantly assumed. Always conscious of its grave responsibility, it has, in exercising the legislative powers conferred upon it, endeavored to fortify its position with authoritative opinion and advice, and for many years it has been the practice of the department, when considering new legislation to correspond with the advance of medical science, to call into counsel the leading members of the profession and to secure a consensus of expert opinion before taking action. In order to systematize consultations of this kind there was established some time since a medical advisory board, and among its present members are such men as Dr. H. M. Biggs, state commissioner of health, and Drs. A. Jacobi, Simon Flexner, William M. Polk, and T. Mitchel Prudden. It has been the aim of the present head of the department to make its legislative enactments an expression, not of the will of the three men composing the board of health, but of the civic ideals and the conscious will of the people themselves. Last year, for the first time, the department asked the systematic coöperation and counsel of laymen, as well as of medical men, and early in 1914 an advisory council consisting of 150 representative men and women was organized. One of the chief objects in establishing such a body was to bring into relation with the department representatives of those trades and

interests which, for one reason or another, fall under its supervision and are in daily contact with it; for it was felt that regulations affecting any industry or occupation should not be adopted except with the cognizance and under the advice of representatives of those regulated. The members of this new advisory council, as well as of the medical advisory board, have therefore participated in the revision of the sanitary code; so that, while the code represents finally the judgment of the three officials who voted upon it, it is based upon the research, experience and deliberation of a large body of qualified and interested citizens who were called to consider it carefully, section by section, before it was presented to the board of health for enactment. The death-rate in the city in 1914 was 13.4, the lowest yet recorded, and it is reasonable to allow that this excellent showing was due in some measure to the enforcement of the existing sanitary regulations. It is hoped by the department that by means of the additions which have now been made to these a still lower rate may be reached.

The new sanitary code is composed of eighteen articles, the first being devoted to definitions, while in the succeeding ones the contents are grouped under headings alphabetically arranged. For instance, the subject of one article is animals, and in this there are sections relating to the reporting of glanders and other contagious animal diseases, to the destruction of diseased animals, and to numerous other matters connected with animals, alive and dead. Some of the additions to the code are of special interest. With a view to the prevention of epidemics resulting from food contamination, it is now required that physicians, in reporting cases of typhoid, diphtheria, scarlet fever, epidemic dysentery, and septic sore throat, must state whether the patient is engaged in the handling of milk or other dairy products or is employed as a cook, kitchen helper or waiter. A new section prohibits the distribution from door to door of so-called samples of medicine intended for internal use, a method of advertising which has been quite extensively used to increase the sale of harmful nostrums, and particularly of those containing habit-forming drugs. In regard to the sale of patent and proprietary medicines it is prescribed that the ingredients entering into their composition shall be mentioned on the package or, as an alternative, that the names of such ingredients shall be filed with the health

department. The employment in bakeries of persons suffering from communicable diseases is prohibited by a state law, and under the new code this rule is extended to include persons employed in all places where food or drink is "prepared, cooked, mixed, exposed, bottled, handled, manufactured, offered for sale, or sold." Another section specifies that in the manufacturing, handling and sorting of cigars and cigarettes no person engaged in such work shall at any time touch with the lips, teeth or tongue any cigar, cigarette or tobacco to be offered for sale, and manufacturers are required to post in their establishments warnings against such practices. In factories and other places where, in the regular course of the business, dust, gases, fumes, etc., are generated or released in quantities constituting a menace to health, efficient suction devices must be provided. The owner, lessee, or other person having the management of any salt marsh land, inland swamp, sunken lot, abandoned excavation, or any place on or in which water becomes stagnant, and may thus lead to the breeding of mosquitoes, is required to drain or fill in the place, or to employ such other method as will at all times prevent the breeding of mosquitoes there. The private hospitals in the city which are established and maintained by benevolent corporations, are invariably chartered by the state, but in addition to these there have been operated an increasing number of small private hospitals, not in receipt of public funds, which are not charitable institutions, and which do not come under inspection by the agents of the State Board of Charities. Conditions having arisen which pointed clearly to the necessity for the control and regulation of establishments of this kind, it was decided by the board of health to take action in the matter, and, accordingly, in the new code it is provided that hereafter no person or corporation other than those specifically authorized by law shall "conduct or maintain any private hospital or institution wherein human beings may be treated or cared for by physicians or midwives without a permit therefor issued by the board of health."

ADMISSION TO THE RUTLAND STATE SANATORIUM.

THE Rutland State Sanatorium ever since its opening in 1898, has been reserved, according to

the ruling of the board of trustees, for early and favorable cases of pulmonary tuberculosis. Prior to 1910, when the present board of trustees took charge, applicants for admission to this sanatorium had first to be examined by a special Rutland examiner, who passed upon the patient's fitness as a patient for this institution. There were ten or twelve such examiners scattered throughout the state. In addition to passing this examination, no patient could be admitted unless he or his relatives and friends could provide the necessary \$4.00 a week.

Under this system the average number of really incipient cases at Rutland was about 27-28%, occasionally reaching as high as 32-33% of the whole. The remaining patients were in the advanced or moderately advanced stages of the disease. When the present board of trustees took charge of the Rutland Sanatorium, the old system of special examiners was discontinued and an elaborate application blank was prepared, which any registered physician in this state could fill out and by this means make application for admission to Rutland for his patients. The payment of \$4.00 a week as an essential requirement for admission was also done away with. As a natural result of this change in the method of admission to Rutland, at first the number of incipient cases admitted fell to 18-20%. Gradually, however, as the medical profession became more proficient in the early diagnosis of tuberculosis, the percentage of incipient cases has risen so that now the proportion is about the same or better under the present system than it was formerly under the old system of special examiners. The fact still remains, however, that at present, as in the past, two-thirds or more of the patients at Rutland, an institution supposed to be reserved for the early and favorable cases of tuberculosis, are in the moderately advanced or advanced stages; likewise the unsatisfactory condition continues, in that really favorable patients, especially among men, must wait two to three months and sometimes four months before their names are reached, for admission to Rutland.

In order to improve this state of affairs and to allow of the admittance of early cases without this long delay, the board of trustees at its last meeting, held Jan. 5, 1915, passed the following vote:—

Voted, That whereas the Rutland State Sanatorium is reserved for early and favorable cases

of pulmonary tuberculosis, in future all patients admitted to the Rutland State Sanatorium be placed on trial for a period of one month in order to ascertain their eligibility for this institution. If at the end of this period of one month patients are found not to be suitable cases for the Rutland Sanatorium, they are to be given opportunity of transfer to one of the other state sanatoria and their names placed at the head of the list for this purpose.

It is not believed that this vote will cause any hardship to any patient. Arrangements will be made to transfer patients, who after their period of probation are found to be unsuitable for the purposes of the Rutland Sanatorium, to some other sanatorium or to a local hospital. It will result, it is to be hoped, in shortening the waiting list and in reducing to a reasonable time the period of waiting which incipient and favorable cases of tuberculosis now have to undergo before admittance. It will also result, it is hoped, in making Rutland an institution in fact, as in name, for incipient consumptives, while in addition it ought greatly to improve the atmosphere and morale of the sanatorium. It will doubtless cause considerable discontent and mental anguish among those patients who after a month's time are found not suitable for Rutland and who have to go elsewhere. It will likewise cause some dissatisfaction among physicians who may not agree with the decision reached at the sanatorium. It is hoped, by making this statement and by explaining the reasons for this change and the causes which have made it necessary, that the medical profession of the state will see the wisdom therefor and will coöperate with this board in making the change successful and beneficial.

CONTAMINATION OF FOOD WITH FECAL MATTER.

ALL persons who have had active experience in the effort to improve sanitary conditions in backward rural districts agree that one of the most difficult problems is to convince the people that their water supplies are in reality not so pure as they seem to the unaided senses. If water is clear, cold and plentiful, and devoid of bad taste or odor, the average person, unedu-

ated in the refined methods of modern analysis, is loth to believe that it can carry within its sparkling depths anything so dangerous as the germs of disease. In fact, it has been practically known for a long time that a considerable portion of certain rural populations consumes by accident more or less human excrement, but in order to convince the people themselves that such is the case, some incontrovertible scientific proof was necessary. Believing that such actual demonstration would have a high educative value, Professor Stiles of the Hygienic Laboratory has succeeded in evolving a method for this purpose.*

The fundamental principle underlying the method consists in the fact that certain animal parasites, namely the *entamoeba coli*, *lamblia*, *trichomonas*, *ascaris lumbricoides*, and *trichuris trichiura* are found in the intestines of man only, not being found in the alimentary tract of any animal and having no free living state outside the human intestines, the transmission from person to person occurring in either spore or egg form. Therefore any person who has in his intestines one of these parasites must necessarily have obtained it by swallowing human excrement. The Division of Zoölogy of the Public Health Service applied this test to 2372 persons taken at random in twelve different localities in three states. They found that 425 out of the 2372 had one or more of these strictly human parasites in their stools, thus proving by zoölogical methods alone that 17.9% of the persons examined had unwittingly partaken of food or drink contaminated with human feces.

The impartation of such information to a community grown lax in its personal sanitation and lukewarm to the efforts of health officers to better conditions, should certainly have a salutary effect. Indeed, it would seem that people who failed to be awakened by a knowledge of this kind were hopelessly asleep and incapable of any kind of progress.

MEDICAL NOTES.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER.—A meeting of the American Society for the Control of Cancer was held in Boston on Jan. 14, with addresses by Dr. J. Collins Warren, Dr. Edward Reynolds, and Prof. Dr. W. T. Sedg-

* Annual Report of the Surgeon General, U. S. Public Health Service, 1914, p. 22.

wick, of the Massachusetts Institute of Technology.

THE EPIZOOTIC OF FOOT AND MOUTH DISEASE.—With the gradual subsidence of the epizootic of foot and mouth infection, there is a gradual removal of the national quarantine regulations by means of which the disease has been brought under control. On January 13, the quarantine of livestock was suspended in many counties of Indiana, Kentucky and New York. In Massachusetts movement of livestock in non-infected areas is now permitted.

SOCIETY OF AMERICAN BACTERIOLOGISTS.—The Society of American Bacteriologists held its annual meeting in Philadelphia at the Laboratory of Hygiene, University of Pennsylvania, Dec. 29, 30 and 31, 1914.

The following officers were elected: President, D. H. Bergey, M.D.; vice-president, John Weinzirl, M.D.; secretary-treasurer, A. Parker Hitchens, M.D.; council, K. F. Kellerman, M.D., W. A. Stocking, Jr., M.D., R. E. Buchanan, M.D., R. J. Conn, M.D. Delegate to A. A. A. S., M. J. Rosenau, M.D.

The next regular meeting of the society will be held in Urbana, Illinois. The chairman of the local committee is Professor H. A. Harding. A special meeting of the society will be held in San Francisco during the summer.

PELLAGRA AND POLIOMYELITIS IN MISSISSIPPI.—During the month of November, 1914, 603 new cases of pellagra and nine of poliomyelitis were reported in the state of Mississippi.

TUBERCULOSIS IN NORTH CAROLINA.—In the weekly report of the United States Public Health Service for Jan. 15, is reprinted the following extract from the message of Governor Craig to the North Carolina General Assembly on Jan. 7. It evidences well his appreciation of the seriousness of the problem of state control of tuberculosis and indicates some of the measures which it is expected may be taken in North Carolina to meet it:—

“The problem of dealing with tuberculosis is most serious. In North Carolina it has been ascertained that 18,000 people are the victims of this disease. Many may have it of whom we do not know. It is an ever-present plague that stalks abroad at noonday, and one-seventh of all the deaths in the state are from this dreaded disease. The state sanatorium was established in response to the demand that something must be done for the afflicted, and to stop the ravages of the plague. In my opinion this institution, with its present scope and efficiency, is utterly incapable of dealing effectively with the situation. As an institution for the purpose of educating people to care for themselves and disseminating knowledge of the disease, it cannot be as effective.

tive as could a bureau established for the purpose of sending literature to every person in the state known to be afflicted. Such literature could present the situation more intelligently to the people and with more efficacy than could be done by a few patients who are fortunate enough to secure admission to the small establishment at Sanatorium. There are now about 90 patients in this institution. It is most humanely and most ably managed. Yet it is altogether inadequate to deal with this stupendous proposition that so vitally affects the people. It has done good in individual instances, but there are thousands in the state who cannot gain admittance, and who will desire admittance when its efficiency is recognized. This institution can never care for those entitled to admission. On the present plan, the whole revenue of the state could not meet the demand. *It is one of the highest obligations of the state to deal with this disease, to do all possible to prevent it, and to cure those who have it.* I hope that this general assembly can work out a practical method that will be effective."

ASSOCIATION OF LIFE INSURANCE PRESIDENTS.—The recently published proceedings of the eighth annual meeting of the Association of Life Insurance Presidents, held in New York City on Dec. 10 and 11, 1914, includes several papers on the relations of life insurance to questions of public health. Among these may be mentioned one by Mr. Rudolph Hering on the "Relation of Sanitary Engineering to Public Health," and one by Mr. Arthur Hunter entitled "Can Insurance Experience be Applied to Lengthen Life?" Mr. Hering summarizes the work and methods of sanitary engineering under six groups, dealing respectively with water supply, air supply, street cleaning, river cleaning, refuse removal and sewerage removal. In all these he concludes that public works relating to sanitary engineering have reached a point of development based on sufficient knowledge and experience to present satisfactory solutions in practically all cases. Mr. Hunter believes emphatically that insurance experience can successfully be applied to lengthen life. The statistics gathered by insurance companies are particularly of value from the information which they afford relative to hazardous occupations, tuberculous family history, history of important infections such as rheumatism, typhoid, or syphilis, cardiac and renal physical defects, addiction to alcohol and excessive emaciation or obesity.

EUROPEAN WAR NOTES.—On Jan. 13 a Japanese Red Cross unit sailed from New York aboard the *Megantic* for Southampton, England, where it will be stationed at the Netley Royal British Naval and Military Hospital, to which it has been assigned for duty. The unit consists of Surgeon-General Suzuki, Dr. T. Oshima, and 21 nurses.

On Jan. 16 a cargo of sera, antitoxins, adhesive plaster, bandages, and 1500 pounds of chloroform was shipped to London from the American Red Cross at New York aboard the *Minnetonka*.

The American Field Ambulance Association, Incorporated, has been formed by Charles E. Cotting of Boston, Robert Walcott of Cambridge, Frank Cheney, Jr., of South Manchester, Conn., Theodore S. Farrelly of New York City, and Samuel Thorne, Jr., of Rye, N. Y. The objects of the corporation are to operate a field ambulance service in France, Belgium and elsewhere, to relieve the sick and wounded, and perform such other work as may seem necessary, and to acquire such property as these purposes of the corporation shall require.

The principal office of the corporation is at 19 Cedar Street, New York City. The organization is neutral and is operating subject to the rules of the Geneva Convention, which entitles its members to wear the red cross. For financial support it depends entirely on the generosity of Americans, and since the need of funds to maintain equipment and support the personnel is urgent at present, contributions may be sent to any of the incorporators or to Samuel Thorne, Jr., treasurer, 19 Cedar Street, New York City.

An unauthenticated report in the public press states that Dr. Alexis Carrel, at his hospital in Lyons, France, has succeeded in grafting an entire forearm and elbow-joint from a moribund to a wounded patient. If this be true, it is not only a great personal triumph for Dr. Carrel, but a demonstration of the value of experimental surgical research.

On Jan. 23 the total of the New York Belgian relief fund amounted to \$862,573.52; the New York Red Cross fund to \$444,312.76; the New York Jewish relief fund to \$320,097.36; the American Ambulance Hospital fund to \$312,397.15; the Prince of Wales fund to \$105,763.88; and the American Polish relief fund to \$16,851.37.

On Jan. 24 the total of the New England Belgian relief fund amounted to \$179,287.17; the Massachusetts Red Cross fund to \$103,297.66; the Boston branch of the American Ambulance Hospital fund to \$51,636.45; the New England Jewish relief fund to \$27,273.35; and the Boston Polish relief fund to \$14,154.97.

MORTALITY FOR WEEK ENDING JANUARY 15, 1915.—The Department of Health yesterday gave out the following figures concerning the mortality during the week ending January 16: The increase in the mortality from acute bronchitis, lobar pneumonia and broncho-pneumonia, to which attention was called in last week's bulletin, continued during the past week, the number of deaths totalling 311 as against 246 during the corresponding week in 1914. The increased mortality from these causes was more than offset by the decreased mortality from certain other

causes, especially measles, scarlet fever, pulmonary tuberculosis, Bright's disease and nephritis and violence, so that the death-rate from all causes combined was 14.49 per 1000 of the population, against 14.86, a decrease of .37 of a point, which is equivalent to a relative decrease of 41 deaths in the week's mortality.

The increase in the mortality during the past week was chiefly among children under five years of age, and especially so among children under one year of age, there being 51 more deaths reported at this latter age group. The mortality at the other age groups was somewhat lower than in the corresponding week of 1914.

The death-rate for the first three weeks of this year was 14.73 per 1000 of the population, as against 14.62 during the corresponding period in 1914, an increase of .11 of a point.

HARVEY LECTURE.—The seventh in the current series of lectures before the Harvey Society will be delivered on Saturday evening of this week, Jan. 30, at the New York Academy of Medicine, by Professor Hans Zinsser, of Columbia University, on "The More Recent Developments in the Study of Anaphylactic Phenomena."

BEQUEST TO THE ROCKEFELLER INSTITUTE.—The will of the late Henry Rutherford, recently admitted to probate, contains a bequest of \$200,000 to the Rockefeller Institute for cancer research.

BOSTON AND NEW ENGLAND.

LAWRENCE MATERNITY ASSOCIATION.—The Lawrence (Mass.) Maternity Association has been formed to aid those women whose circumstances do not permit the employment of regular medical attendance with nursing, at time of childbirth. The central office at the Lawrence General Hospital will be open at all hours, day and night. Patients may register, and the services of physicians and nurse may be secured. It is urged that registration be made at least three months before expected labor, thus giving the patient the benefit of the nurse's visit beforehand. Care and instruction will be given from time to time by the physician and nurse, and the patient will receive daily visits after delivery as ordered by physician. A moderate fee will be charged for services, which will be explained at time of registration.

AESCULAPIAN CLUB OF BOSTON.—The mid-winter meeting of the Aesculapian Club of Boston was held at the Harvard Club on Saturday evening, Jan. 9, being preceded by a dinner of the club at which were 103 members and the guests, Dr. Oscar Dowling, president of the Louisiana Board of Health, and Mr. Norman Hapgood, editor of *Harper's Weekly*. The meet-

ing was at 9 p.m., there being present, beside the members, about 125 guests. The first speaker, Dr. Dowling, gave a very interesting talk, narrating in some detail the history of his board from early days, its present trials and successes, its tour of the state with cars of exhibition and instruction, and its methods and results in cleaning up various objectionable towns and places. Mr. Hapgood's talk was general and on the whole well chosen and complimentary to the profession. He touched on the failure of segregation in the regulation of prostitution, on the magnitude of the question of prohibition, on the dissatisfaction of the public in regard to the "alienist" testimony of experts at trials, and on various other matters.

ANNUAL MEETING BOSTON MEDICAL LIBRARY.

—At the annual meeting of the Boston Medical Library, held Jan. 12, 1915, the former officers were reelected: Dr. John W. Cummin was elected to the committee on library and finance, in place of Dr. Morton Prince, who retired after sixteen years service; Dr. Reginald Fitz became a member of the committee on medical and social meetings; Dr. Daniel F. Mahoney a member of the committee on membership and elections; and Dr. Walter Channing and Dr. John W. Bartol were elected vice-presidents. Dr. Francis W. Peabody gave an interesting talk, illustrated by the stereopticon, on "Western Medicine in China." According to the report of the librarian the library now contains 82,275 books and 57,035 pamphlets and use of its facilities has been made by 14,105 readers during the past library year, two-thirds of these being medical students and the public. The number of readers has shown a progressive increase from year to year. The total membership of the library is now 742, a gain of 43 over that of last year.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Jan. 19, 1915: Diphtheria, 63, of which 2 were non-residents; scarlatina, 65, of which 5 were non-residents; typhoid fever, 3; measles, 64; tuberculosis, 45, of which 2 were non-residents. The death-rate of the reported deaths for the week was 16.40.

Massachusetts Medical Society

FRANKLIN DISTRICT MEDICAL SOCIETY.—The Franklin District Medical Society held a meeting at the rooms of the Greenfield Club, Greenfield, on Jan. 12, 1915, the program being entitled "Health Day." Dr. J. E. Urquhart of Ashfield, president, was in the chair, and Dr. G. P.

Twitchell of Greenfield acted as secretary. Dr. William C. Hanson read a paper on "The Functions of the State Department of Health"; Dr. Francis G. Curtis, chairman of the board of health of Newton, read on "The Benefit to the Community of the Health Office"; Mrs. William Lowell Putnam of Boston on "The Benefit to the Producer of Clean Milk." The papers merited the interesting discussion which followed, bringing out the needs of better medical education and standards in the country districts. The following took part in the discussion: Dr. J. S. Hitchcock, state inspector of health for the Northampton district, Dr. N. P. Wood and Mr. Moody of Northfield, Dr. P. W. Goldsbury of Warwick, Dr. Urquhart of Ashfield, Drs. B. P. Croft, G. P. Twitchell and F. W. Donahue of Greenfield, Dr. H. A. Sutor of South Deerfield and Messrs. Covell of Shelburne and George Moore of Greenfield.

9. HUSKIN, A. L. *Pomphigus Follicaceus Neonatorum.*

1. Lydston reports a case of late syphilis of the cranium and spine without symptoms referable to the bony structures involved, and without disturbance of brain or nerve function. Such lesions, he says, are due not to pressure or corrosion but to perversion of nutrition resulting from luetic toxemia which affects

especially the sympathetic system. In cases of this sort the bones of the face are more often selected than those of the cranium and spine, the tissues supplied by the fifth nerve being particularly susceptible. There may or may not be gummatous infiltration elsewhere. The treatment is necessarily surgical as well as specific. [L. D. C.]

15. MAYORAL, A. *Report of a Case of Acute Dilatation of the Stomach.*
16. BOSMOT, E. *Quinin Salts in Post-operative Cases. Preliminary Report.*

1. Williams in an exhaustive analysis shows that syphilis is far and away the most common etiologic factor concerned in the production of death, presenting an incidence of 26.4%. Toxemia, including eclampsia and nephritis, accounted for only 6.5% of deaths; 17.4% were due to dystocia. The article is of much interest and value.

3. These authors, while not underrating the phenolsulphonephthalein test for renal function, contend clinical data and surgical necessity should be the determining factors in deciding whether an operation is or is not necessary.

7. Novak is an advocate of this form of treatment.

10. Eisendrath shows experimentally the dangers of collargol or any substance injected into the renal pelvis under pressure or in too large amounts. He, however, claims that there is no danger in the human subject, provided ordinary care is taken not to use pressure or large amounts. [E. H. R.]

1, 2, 3, 5. These articles are of interest, but not particularly suited to review.

6. This paper is of considerable practical interest and well illustrated by plate.

9. Smith shows that after the intravenous injection of 6 mg. phenolsulphonephthalein, each kidney of a normal pair begins to excrete the dye in about 3 minutes, and in the next 15 minutes puts out about 5%. If a sound kidney, which has a diseased fellow, excretes 15% it is at least equal to one normal kidney; if more than that it is already taking up the work of both. Such a kidney may put out 30% in this period, or as much as two normal kidneys combined.

10, 11. These two papers are an interesting and valuable review and contribution to this subject.

20. *BROWNE. *The Production of Acid by the Bacillus Coli Group.*

1-10. Kendall, Day and Walker print a series of ten papers upon "Studies in Acid-Fast Bacteria," from which the following conclusions have been reached:—

Young, rapidly growing tubercle bacilli are, in part at least, non acid-fast. During the first three weeks of growth of the tubercle bacillus in plain and sugar media there is a rapid accumulation of ammonia, which later gradually, but definitely, recedes.

Early in the growth of the tubercle bacillus the nitrogen of the media is markedly diminished. Later much of the "lost" nitrogen reappears. The reappearance of nitrogen is coincident with the loss of vegetative activity of the organism and is possibly due to autolysis. Similar results were found with other members of the acid-fast group, notably the smegma and the grass bacillus.

All forms of acid-fast bacilli produce in a wide variety of media a free, soluble, thermostable, non-diffusible lipase during the period of active development, the activity of which is proportionate to the luxuriance of growth of the organism. The lipase curve is parallel to that of the ammonia. Washed tubercle bacilli also contain such a soluble lipase, although it is less active than that previously freed from the bacilli. It is impossible to state whether this soluble lipase, found free in the media, is a result of autolysis or is an exolipase.

15. Copper, introduced into the guinea-pig in all forms and in every manner, has no effect upon tubercular lesions. It is suggested that this is due to the fact that all such salts become in the body colloidal copper, which cannot penetrate the tubercle or other necrotic areas.

19. The addition to culture media appropriate for the growth of the tetanus bacillus of gentian violet inhibits growth when in proportion of 1:10,000; prevents growth without the destruction of the organism in 1:100; and destroys its virulence in 1:10. The practical application of this agent in the laboratory is precluded by the excessive soiling of apparatus by such strong solutions as are necessary to secure avirulence.

20. Browne, in a most interesting and complete article upon acid production by the coli group, states that maximum fermentation takes place in 20 hours at 37°C., provided 0.5 c.c. of a 24-hour peptone culture be used as an inoculum, and the carbohydrate be present in 1% solution. The extent of acid production depends, not on the amount of media nor the power of the organism to ferment, but upon the tolerance of the particular strain to the acid itself. This is clearly

demonstrated by further acid production following neutralization of the acid already formed. This may take place until the carbohydrate is completely exhausted. The greatest amount of acid is produced in media containing the monosaccharids, less from the disaccharids, and least from Raffinose, a trisaccharid. [L. H. S.]

14. *MAJOR. *The Pathological Anatomy of the Pancreas in Diabetes.*

10. Floyd concludes from a series of animal experiments that acute pleuritis, whether dry or associated with serous or purulent exudates, is essentially a pathological unit. The extent of the process and the nature of the fluid depends upon the virulence of the infection, the body resistance and the extent of chemiotaxis which the infecting organism excites.

12. In 100 psychopathic autopsies, Southard and Canavan found gross or macroscopic renal involvement in every instance. In many cases, however, the extent of this process had little clinical significance. Chronic interstitial nephritis was demonstrated grossly in 42%, microscopically in 66%. These figures are striking and are of considerable importance. Detailed study of the occurrence of plasma cells in the kidney substance, and the relation between their presence and certain psychopathic states follows.

14. Major found the islands of Langerhans in diabetes normal in 41% and the seat of fibrosis in 46%. In 46% of the latter hyaline degeneration was found, which was the most striking and constant lesion associated with diabetes, since in only one instance was it found in a non-diabetic case. The inevitable conclusion is drawn that no anatomical evidence exists to prove the diabetes is due to pancreatic disease.

1. Oppel's comprehensive contribution is based upon an experience of 41 cases of resection or exclusion of the large intestine. He warns against the formation of a cul-de-sac. If this cannot be avoided he recommends making a mucous fistula at the proximal end of the cul-de-sac. He condemns the unilateral exclusion of the large intestine effected by means of ileocolostomy with division of the distal portion of the ileum. The Giordano—Bergmann operation (caeco-sigmoidostomy) and Montprofit's (division of ileum and double implantation into sigmoid) are carefully considered and condemned. An economical (short loop) partial unilateral exclusion (entero-anastomosis) is favorably regarded for non-malignant obstructions (pericolic contractions, kinks and benign strictures). For such conditions at the flexures colocolostomy (transverse to ascending or to descending) with short loop is considered rational and leaves no culs-de-sac. An exception to preference of partial unilateral exclusion over complete unilateral exclusion is in strictures of the cecum. Here ileo-transversostomy with division of the distal ileum is better than same anastomosis without ileal division. In case of difficulty in bringing the ends of the colon together after resection (resection of ascending and transverse colon), Oppel suggests a high ileocolostomy (not an ileo-sigmoidostomy) with formation of mucous fistula at top of right hand cul-de-sac. Appendicostomy is considered worthy of wider recognition.

2. Jones and Whitman report fully and discuss at length a case of primary sarcoma of the lower end of the femur, involving the synovial membrane. Exploration with removal of section for microscopical examination revealed the nature of the condition. High thigh amputation was performed, but the patient died in three months of metastases in the lungs. Prints of x-rays and photomicrographs are given. The literature has been searched and only 17 cases found.

8. Mann's paper is based upon an experience of 44 cases of fascial and tendon transplants in animals and several in man. He gives in detail the use of two strips of ilio-tibial band to strengthen a large umbilical hernia and of one strip to strengthen a Bassini operation. He pictures the use of fascia to strengthen a Ferguson operation. He emphasizes the importance of laying the transplant *in situ* so that its fibres are "on the stretch."

9. Whitman clearly sets forth his abduction treatment of fractures of the neck of the femur. He points out the greater certainty of contacting the fragments and of maintaining their contact by this method. Age is no contra-indication. In fact, the possibility of raising the head of the bed instead of the necessity of raising the foot of the bed in extensive treatment diminishes the likelihood of hypostatic congestion, and the possibility of turning the patient instead of the enforced rest upon the back in extension treatment diminishes the likelihood of bed sores. [T. W. H.]

Obituary.

DUDLEY P. ALLEN, M.D.

DR. DUDLEY P. ALLEN, an eminent surgeon of Cleveland, Ohio, died in New York City on Wednesday, Jan. 6, 1915. Throughout his active and useful life he was so often and so closely identified with Boston, and he has had so many professional friends and acquaintances here, that his death calls for more than a passing notice in these columns.

Dr. Allen was born in Kinsman, Ohio, March 25, 1852. Both his father, Dr. Dudley Allen, and his grandfather were physicians. After graduating from Oberlin College in Ohio, he came to the Harvard Medical School, where, after following the usual course, he received the degree of M.D. During the year 1879-1880 he was surgical house-officer in the Massachusetts General Hospital, being assistant to Drs. Samuel Cabot, J. Collins Warren, and C. B. Porter; and it was in that school of surgery—where he was also associated with Drs. Henry J. Bigelow, Richard M. Hodges, H. H. A. Beach, John Homans and others—that he developed an intense interest in the practical side of surgery, and began a career which in course of time brought him to the front rank among the surgeons of the country. After finishing his term of service at the hospital he went to Europe, where he passed several years attending lectures and following the work at all the best clinics, especially the surgical ones, in Berlin, Leipzig, Freiburg, Vienna, London and Paris. On returning to America in the early 80's he settled in Cleveland, and began to teach and practise surgery. He soon became lecturer on surgery at the Western Reserve Medical School, and later was appointed professor of surgery and clinical surgery.

Dr. Allen was early given a position on the staff of the Lakeside Hospital, and for many years he was visiting surgeon in that institution, having in charge a very large clinic. His private practice grew rapidly, until, as a surgical consultant, his services were in constant requisition all over the state of Ohio, and even beyond its boundaries. He was greatly interested in the development of the Cleveland Medical Library, and gave to that institution material assistance in many different ways. Finally, he was chosen president of the Ohio State Medical Society. As time went on he came even more and more to the front, for his intelligence, courage, and industry, and his deep interest in all problems connected with medicine and surgery brought him into prominence throughout the country. For years he was secretary of the American Surgical Association, and finally (1906-1907) he was president of that association. In 1906 he was elected Honorary Fellow of the Philadelphia Academy of Surgery, and in 1908 Oberlin College conferred upon him the degree of LL.D.

During all this time Dr. Allen frequently came to Boston; sometimes for the purpose of reading papers on professional subjects, and at other times to study methods of operation and instruction. He always preserved the keenest interest in the medical practices and traditions of Boston. In 1910 he resigned all his medical positions and retiring from active practice, started with his wife (formerly Miss Elizabeth S. Severance of Cleveland) on a tour around the world. On his return to Cleveland after this long journey, a banquet was given in his honor by his medical colleagues, and the large attendance and the cordial and dignified character of the addresses attested the warm affection and the high esteem in which he was held.

Dr. Allen's interests were not limited to professional fields. Both music and art claimed a large share of his attention. His superb collection of engravings, etchings, pictures, and porcelain includes many rare specimens of the choicest variety. He was a recognized expert throughout the country in old Chinese porcelains. Undoubtedly it was because of his great knowledge of art, and of his love for it, that he was made a trustee of the Cleveland Museum of Art. He was also deeply interested in religious and philanthropic work, as well as in many other directions.

He died of pneumonia after a few days' illness.

He had many lovable characteristics, and was a loyal friend. His loss will be keenly felt by those who had the privilege of knowing him well. He was one of those men whose virile intelligence, persistent industry, and deep-seated humanity have done much to elevate the tone of the profession in this country, and to widen the sphere of its influence.

G. H. M.

Miscellany.

CONTAMINATION OF LAKE WATERS.

IN last week's issue of the JOURNAL we published an editorial commenting on the contamination of lake waters and the consequent risk of disseminating typhoid and other enteric diseases by the use of such waters for drinking purposes. In anticipation of action by the United States Public Health Service, the Erie railroad lake lines have issued the following regulations governing the water supply aboard their ships and its protection:—

“The health of the ship's company is fully as important as the safety of the ship and its cargo, and the supervision of the water supply will be

the care of the master exclusively and cannot be delegated by him to any one.

"Isolated sources of supply and methods of distribution have been, or will be, provided, and under no circumstances will the tanks be filled from or through any other. The sea cock will be kept locked and the key be in the possession of the master.

"When water is to be taken, the master will give, or send, the key to the engineer on duty, who will personally see that the sea connection is thoroughly boiled out by means of the steam connection provided for the purpose for at least five minutes before opening the sea cock. The engineer will also personally close and lock the sea cock and return the key to the master.

"Water tanks are to be thoroughly cleaned and scrubbed out with a strong caustic solution at least one in each month and the solution drained and flushed away through the distribution service.

"Except in case of fire, buckets or other vessels are not to be dipped into tanks, and every effort is to be made to keep them free from contamination.

"In taking water, masters will exercise due caution with regard to ships ahead and haul courses, if necessary, to clear their wake.

"Drinking cups or vessels used in common should be thoroughly boiled at frequent intervals or discarded, and the use of water buckets as containers for drinking water should be discouraged, as far as possible. When used in fire holds, they should be boiled out frequently with the steam hose.

"Natural ice is not to be taken aboard under any circumstances unless artificial is unobtainable, and then only when its source is clearly known and satisfactory, and in quantity only sufficient for immediate needs. Ice boxes should be thoroughly scrubbed out after any such supply of doubtful quality."

SCHOOL FOR HEALTH OFFICERS.

HARVARD UNIVERSITY AND MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

A SERIES of afternoon lectures at the Harvard Medical School from 5 to 6 p.m. Undergraduates and instructors of the Harvard Medical School and of the Massachusetts Institute of Technology may obtain free cards of admission to the entire course by applying to the Director, Dr. M. J. Rosenau Harvard Medical School.

1. *School Hygiene*—Dr. T. F. Harrington, Director of Hygiene in the Boston Public Schools. Three lectures, February 10, 17 and 25, supplemented by practical exercises.

2. *Hygiene in the Tropics*—Dr. Richard P. Strong, Professor of Tropical Medicine, Harvard Medical School. Six lectures, April 7, 28 and May 5, 12, 19 and 26.
3. *Sanitary Law—Legal Powers of Health Officers*—Prof. Eugene Wambaugh, Professor of Law, Harvard Law School. Six exercises, April 1, 6, 8, 13, 27 and 29.
4. *Infant Mortality*—Dr. John L. Morse, Associate Professor of Pediatrics, Harvard Medical School. Three lectures, March 29, April 5 and 12.
5. *Ocular Hygiene*—Dr. F. H. Verhoeff, Instructor in Ophthalmic Pathology, Harvard Medical School. Two lectures, March 15 and 16.
Illumination—Dr. Louis Bell, Electrical Engineer. One lecture, March 17.
6. *Oral Prophylaxis*—Dr. W. H. Potter, Professor of Operative Dentistry, Harvard Dental School. Three lectures, May 6, 13 and 20.
7. *Personal Hygiene*—Dr. W. B. Cannon, Professor of Physiology, Harvard Medical School. Six lectures, February 9, Exercise; February 12, Fatigue; February 16, Rest; February 19, Bathing; February 23, Clothing; February 26, Diet.
8. *Medical Inspection of Immigrants*—Dr. M. V. Safford, U. S. Public Health Service, Medical Inspector of Immigrants, Boston. Two lectures, March 19 and 26, supplemented by practical exercise.
9. *Veneral Prophylaxis*—Dr. E. H. Nichols, Associate Professor of Surgery, Harvard Medical School. One lecture, Friday, April 30.
10. *Municipal Sanitation*—Dr. C. V. Chapin, Supt., Board of Health, Providence, R. I. Three lectures, April 26, May 3 and 10.
11. *Relation of Animal Diseases to Public Health*—Dr. Theobald Smith, Professor of Comparative Pathology, Harvard Medical School. Six lectures, March 1, 3, 5, 8, 10 and 12.
12. *Mental Hygiene*—Dr. E. E. Southard, Professor of Neuropathology, Harvard Medical School. Six exercises, February 18, 25, March 4, 11, 18 and 25. Given at the Psychopathic Hospital.
13. *Diet and Pellagra*—Dr. Joseph Goldberger, Surgeon U. S. Public Health Service, Washington. One lecture, April 2. (Cutter Lecture in Preventive Medicine—open free to press and public.)
14. *The Phenomena of Infection*—Dr. Victor C. Vaughan, Professor of Hygiene and Physiological Chemistry and Dean of the School of Medicine and Surgery, University of Michigan. Three lectures, April 14, 15 and 16. (Cutter Lectures in Preventive Medicine—open free to press and public.)
15. *Tuberculosis*—Dr. John B. Hawes, 2d, Secretary Board of Trustees, Massachusetts Hospital for Consumptives. Six lectures, February 1, 4, 5, 8, 11 and 15, supplemented by four practical exercises.
16. *Posture and Prevention of Deformities*—Dr. R. W. Lovett, Assistant Professor of Orthopedic Surgery, Harvard Medical School. Three lectures, March 22, 23 and 24.
17. *Social Service*—Dr. Richard Cabot, Assistant Professor of Clinical Medicine, Harvard Medical School. One lecture, March 9, supplemented by practical exercises under the supervision of Miss Ida Cannon at the Social Service Department of the Massachusetts General Hospital.

Correspondence.

EARLY PICTURES OF ACROMEGALY.

BOSTON, January 11, 1915.

Mr. Editor: In the *Lancet* for December 19, in an article entitled "A Case of Acromegaly 200 Years Ago," Dr. Leonard Mark calls attention to the paintings of Richard Dickinson, who lived at Scarborough, England, 1670-1738. There are seven original paintings by different artists, one by Virtue in 1725, showing a typical acromegalic facies. Mark speaks of this being one of the earliest representations of a rare disease, only recognized of late years, and states that, to his knowledge, it is the earliest picture of an acromegalic to be found in England. He speaks of two other representations to be found on the continent at an earlier date; one, the portrait of a giant at the court of the Elector of the Palatinate, Frederick II, which was painted in 1553; another is the carved figure of a woman, about the 13th century, which is or was on a flying buttress of Rheims Cathedral. There is little hope of its being still extant. In connection with this subject, an exhibition of miniatures at the Boston Public Library from the Grimani Breviary is of interest. This breviary contained nearly 2000 pages and was the masterpiece of the Flemish miniature paintings. It dates from the 15th century. Some of the paintings are thought to be by Hans Memling. No. 1571 is the picture that interests us in this connection. It is of St. Catherine disputing with the doctors (3d century). Without doubt, contemporary Flemish faces (15th century) were the models. This picture is by an unknown artist. In the group around St. Catherine are two figures which stand out unquestionably as typical acromegalics, the immense prognathous jaw, and large face in one figure being particularly interesting. One of the lower figures had also typical facial characteristics. In the other fifteen pictures, some of sacred subjects, some of profane, there is no hint of an acromegalic face, though the broad features of the Flemish type are faithfully portrayed.

Very truly yours,

WM. PEARCE COUES, M.D.

BELGIAN PHYSICIANS' RELIEF FUND.

In his stirring appeal for aid for the Belgian physicians, Professor Charles Jacobs of Brussels states that 2000 doctors are poverty-stricken, and that 2000 to 3000 doctors are suffering cruelly through this war.

That 2000 physicians need to be supplied the necessities of life would seem a low estimate. It seems probable that the physicians' families will average four members. That means 8000 members of physicians' families are dependent upon outside contributions. \$440 will supply sufficient food to sustain life for one month. Belgian physicians and their families therefore, absolutely need at least \$8800 worth of food every month.

For the first month, contributions of American physicians aggregated \$1414. Will the medical profession of America accept its opportunity and meet its share of this responsibility by prompt and repeated contributions?

Every cent of every dollar contributed will be available for the purchase of supplies as the carrying charges are provided for by the American Commission for Relief in Belgium.

The first one thousand dollars contributed have been expended by the Executive Committee for food and supplies, and the packages properly labeled have been started for their destination.

By order of the Executive Committee.

HOWARD C. TAYLOR, M.D., *Secretary*.F. F. SIMPSON, M.D., *Treasurer*.

THE CUTTER LECTURES.

The Cutter Lectures in Preventive Medicine for the year 1915 will be given at the Harvard Medical School by Dr. Victor C. Vaughan, Professor of Hygiene and Physiological Chemistry and Dean of the School of Medicine and Surgery of the University of Michigan, and Dr. Joseph Goldberger, Surgeon, United States Public Health Service, Washington, D. C.

Dr. Vaughan will lecture on "The Phenomena of Infection" on April 14, 15 and 16.

Dr. Goldberger's subject will be "Diet and Pellagra" and will be given in one lecture on April 2.

These lectures are given annually under the terms of a bequest from John Clarence Cutter, whose will provided that the lectures so given should be styled the Cutter Lectures on Preventive Medicine, and that they should be delivered in Boston, and be free to the medical profession and the press. Others interested are cordially invited.

ROGER PIERCE,
University 5, Cambridge.

APPOINTMENTS.

UNIVERSITY OF OREGON.—Dr. Howard D. Huskins, of Western Reserve University, has been appointed professor of biochemistry in the medical department.

NOTICES.

Physicians visiting the city will be cordially welcomed at the following clinics on the days and hours specified.

BOSTON CITY HOSPITAL.—After January 1, 1915, public operations will be performed in the Surgical Amphitheatre each week, on Thursdays, Fridays and Saturdays, at 10 o'clock.

Thursday: First Surgical Service. Dr. Blake.
Friday. Third Surgical Service. Dr. Nichols, and Fourth Surgical (G-U) Service. Dr. Thorndike.

Saturday: Second Surgical Service. Dr. Lund.
Notice of these operations will be sent to anyone expressing his desire to receive it.

CARNEY HOSPITAL.—Dr. Bottomley and Dr. Mahoney will hold an operative surgical clinic every Wednesday at 9 A.M., and at the same hour on the same day Dr. W. R. MacAusland will hold an orthopedic clinic. All physicians are welcome to attend.

MASSACHUSETTS GENERAL HOSPITAL.—1. A surgical clinic Tuesday, at 12, in the out-patient amphitheatre. 2. Operations in the Bigelow amphitheatre Saturdays from 10 to 1. 3. Operations in the Surgical Building except Sunday, from 9 to 1. 4. Daily surgical ward visits at which visiting physicians will be welcome. 5. Clinic in medicine and pathology Tuesdays at 12, by Drs. R. C. and H. Cabot and O. Richardson. 6. Medical clinic Thursday at 12, by Dr. D. L. Edsall.

PETER BENT BRIGHAM HOSPITAL.—Physicians visiting the city will always be cordially welcomed at the Peter Bent Brigham Hospital.

The medical visit takes place regularly every morning beginning at 10 o'clock.

Operations are usually going on throughout the forenoon in the surgical amphitheatre.

The surgical clinic is held in the clinical amphitheatre on Wednesdays at 12.30 p.m.

The medical clinic is held in the clinical amphitheatre on Mondays at 12.30 p.m.

The clinico-pathological demonstration is held in the clinical amphitheatre on Fridays at 3.30 p.m.

SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library Friday, January 29, 1915, at 8.15 p.m.

The following papers will be read:

1. "Acidosis in Children," Arthur A. Howard, M.D., Boston.

2. "Parenteral Immunization in Conditions of Prolept Sensitization," J. L. Goodale, M.D., Boston.

3. "Weaning—Its Relation to Anaphylaxis as Shown by Differential Blood Counts," H. C. Berger, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*

R. M. SMITH, M.D., *Sec'y.*

NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.—Stated meeting at United States Hotel, Boston, Thursday, February 4, 1915, at 11.30 A.M.

Reader: Edwin A. Locke, M.D., of Boston, for George M. Sheahan, M.D., of Quincy, Mass.

Subject: "Some Considerations in the Medical Treatment of Multiple Arthritis."

F. H. MERRIAM, M.D., *Secretary*,
South Braintree, Mass.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.—The Spring meeting will be held in Sprague Hall, Medical Library, Boston, on Wednesday, February 3, 1915, at 2 o'clock.

The following papers will be read and discussed:

1. "Observations on the Mentality of Certain Criminals," Edward B. Lane, M.D., of Boston.

2. "A Case of Death from Double Pneumothorax," George L. West, M.D., Medical Examiner, of Newton.

3. "Accidental Death from a Stray Shot from Unusual Distance," Charles W. Milliken, M.D., Medical Examiner, of Barnstable.

OLIVER H. HOWE, M.D.,
Recording Secretary.

RECENT DEATHS.

DR. SAMUEL AUGUSTUS FISK, who died on Jan. 18 in Boston, was born on Feb. 9, 1856. He received the degree of A.B. from Yale in 1877 and that of M.D. from Harvard in 1880. From 1884 to 1899 he was a professor in the medical school of Denver University. In 1900 he returned to Boston, and in 1905 settled at Brimfield, Mass. He was a member of the Association of American Physicians, the American Climatological Association, and the National Association for Study and Prevention of Tuberculosis. He is survived by his widow.

A STUDY OF CHILDREN WITH POSITIVE SKIN TUBERCULIN REACTIONS.*

BY ORVILLE F. ROGERS, JR., M.D., BOSTON.

[From the Children's Medical Department, Massachusetts General Hospital.]

THIS study was made at the suggestion of Dr. Fritz B. Talbot, from the records of the Children's ward of the Massachusetts General Hospital, starting with the establishment of that ward on July 1, 1910, and running up to July 1, 1913. Therefore the results here reported deal with children who have been out of the hospital at least one year and not over four years. The average of those heard from was two years, four months.

Those children are included on whom a Von Pirquet (skin tuberculin) reaction was done in the usual manner, with positive results. There were 69 of these in the three years. A number of positive cases were discovered in doing routine skin tuberculin tests, where there was no reason to suspect tuberculosis. These are included in this report, while obvious tuberculosis, in which the skin test was negative, is excluded.

The knowledge of the present condition of these children was gathered from various sources in August, 1914. Some came into the hospital in response to letters, others wrote, and the outpatient records were also used. In all we gained sufficient evidence about 42 children to warrant including them in the report. In addition to this we have eight who died in the hospital—a total of 50 out of 69 whose fate is known with more or less certainty.

* Read at a meeting of the New England Pediatric Society held December 4, 1914.

The table arranged according to age shows that on the whole the younger the patient, the graver the prognostic import of the positive skin reaction. In the first two years of life 11 out of the 17 of whom we know anything, or 65%, are dead. These figures could easily be made to read 11 out of 15, as the two children under one year recorded as alive, might have been left out on the grounds of too fragmentary a knowledge of their after-careers. Neither of these patients apparently had tuberculosis during his hospital stay, but one of them showed signs in his lungs a few months afterwards—since when he has been heard from only indirectly, but is probably alive.

Of that same group of 17, only four—or 23%—have no evidence of active tuberculosis, and only three are really well—a per cent. of 18.

The corresponding figures for children over two years are: known about, 33; dead, 7—21%; alive with no signs of active tuberculosis—21, or 64%; and alive with no illness whatsoever 10, or 30%—almost three times as favorable an outlook.

The second table shows the 69 cases arranged according to diagnosis. In the lowest row of this table are collected the statistics of 24 of the patients—their diseases being non-tubercular, with two exceptions, and none of them having tuberculosis at present as far as known. The two tubercular patients had solitary tubercle(?) and tuberculosis of the right elbow respectively, but nothing has been heard from either of them since discharge.

The most frequent of the tubercular diseases were tubercular peritonitis and pleurisy. Of the five peritonitis cases heard from three had died, while two others are perfectly well. It is interesting to note that these patients either died

of tuberculosis quite promptly or else recovered entirely so far as we know at present. Age apparently did not dictate the outcome, for the two types averaged about the same.

The children who had pleurisy are all in good health if the five who reported are any criterion. The average age of these children is four years.

The cases of miliary tuberculosis and tubercular meningitis perhaps should be classed together but the meningitis cases have been kept separate, as miliary tuberculosis did not appear in the discharge diagnosis. The course of these cases was naturally very unfavorable with the exception of one child who will be alluded to later. The average age of these patients was younger than any other group—two years, two months. It is of interest that two other cases of tubercular meningitis, proven by postmortem, gave negative skin reactions.

The cases of bone tuberculosis of which we have word are not doing well. Both the children with Pott's disease are reported as doing

very poorly, and the little girl with periostitis still has new sinuses forming at intervals.

We have heard from only two of the three patients who had pulmonary tuberculosis, and of these one died of infantile paralysis, and the other still has tuberculosis of the cervical glands—though the lungs appear quiescent.

Glandular tuberculosis was very common, but as it was almost always associated with a more serious disease, which masked it, we can get no clear picture of its effects. One of these patients has since developed pulmonary tuberculosis, and is now in a sanatorium.

The diagnosis of "tuberculosis with otitis media" was made on a little girl of seven months, who gave a strongly positive skin reaction, but in whom the most careful examination failed to locate any focus. She died at Tewksbury one month after discharge from the Massachusetts General Hospital, and the diagnosis sent us from there was marasmus. Therefore she has been

included in the non-tubercular group, thought it is hard to rule out a generalized tuberculosis.

In relation to the question whether children with positive skin tuberculins are predisposed to non-tubercular diseases, it was interesting to find that not one of the 38 patients who had signs of active tuberculosis in the hospital is at present suffering from any non-tubercular affection.

Of the 31 patients who in the hospital showed no signs of tuberculosis save for the positive skin reaction, one has since died of tubercular peritonitis and two more now have signs of activity in the lungs—10%. Many of these have chronic non-tubercular diseases, such as endocarditis, pyelitis, bronchiectasis.

In the group that we know something about there were several interesting cases, about one of which a few words may be said.

He was a boy of four on whom a diagnosis of miliary tuberculosis was made. The history was of anorexia, apathy, and continued fever "for some time." He had enlarged cervical glands, signs of consolidation at both apices, with râles, fluid wave in abdomen, an enlarged liver, palpable spleen, and active reflexes, with a Babinski. In 12,000 white cells he had 54% lymphocytes. No tubercle bacilli in his sputum.

In the course of three weeks the fluid wave disappeared, the other signs remaining the same. He ran a continuous fever, pulse constantly tended upward, and lost weight.

After discharge, according to his mother's story, he remained the same for two to three months and was then sent back to the Cape Verde Islands, where his people came from. There he began at once to gain and now, after three and one-half years, the mother says that he is very well and strong.

While this is only a single case it points to the climatic conditions as being an important factor in this boy's recovery.

In drawing conclusions as to the chances of life for a child who reacts to the Von Pirquet test, we must consider what the mortality is in the average child.

The average age of these children, as it was calculated by adding their ages together and dividing by the number of children, is four years, four months. The average length of time since leaving the hospital was two years, four months. Insurance tables show that of 10,000 children aged four years, four months, 430 would be dead at the end of two and one-third years, a percentage of 4.3.

While the numbers involved in this tabulation are very small the difference between 36% and 4% could hardly be pure chance.

It may be argued that those patients who had an acute form of tuberculosis and died in the Massachusetts General, or were taken home a few days before death, should not be counted in making up our minds as to the probable prognosis of a positive reaction in those who survive. Therefore, eliminating the eight cases which were fatal in the hospital, and one of miliary

tuberculosis which died two or three days after discharge, the figures show that nine out of 41 died, a mortality of 22% instead of 36%, but this is again much higher than the ordinary mortality.

If we still further omit from this number, nine, the four who died of non-tubercular illnesses, and the one of unknown cause, we find that we have four out of 36 who died of tuberculosis at least several months after leaving the hospital—11%—almost three times the mortality of the normal.

SUMMARY.

Before the age of two a positive skin reaction seems to be an indication that the child's life is likely to be short.

The mortality among all children, up to the age of 10, who react to the Von Pirquet test is much higher than that of normal children.

The series is too small, and the time since the tests were made, too short, to permit us to draw any but the most general conclusions.

TWO CASES OF RUPTURE OF INTESTINE.*

BY LINCOLN DAVIS, M.D., BOSTON.

CASE 1. C. C. No. 196642, East Surgical. Seven years old. Schoolboy. Sent to the Accident Room of the Massachusetts General Hospital on July 19, 1914, at 11.05 A. M., by Dr. Alfred Davidson of Chelsea, with diagnosis of "Ruptured Viscus."

The following history was obtained: Previous health always good. Yesterday afternoon at five o'clock patient was running across a field and fell down, striking on a rock. His parents state that they think he fell about six feet. Immediately complained of pain in his stomach and has vomited many times since. Has passed apparently normal looking urine. Patient now has severe abdominal pain.

P. E. Well developed and nourished child, looks very sick. Lungs negative except for dullness at right base. Examined by Dr. W. H. Smith, who says lungs are not responsible for symptoms. Abdomen slightly distended, with marked spasm and tenderness everywhere. Percussion note tympanitic, with obliteration of liver dullness. No shifting dullness made out. On abdominal wall, over left upper rectus, is a contusion and abrasion, 1 inch in diameter. Temperature 100.2 by rectum. Pulse 148. Respiration 36.

Prepared for immediate operation.

Ether anesthesia. Iodine preparation. Five inch muscle-splitting incision carried down to peritoneum. Peritoneum opened with escape of much fluid and fecal material. Fluid baled out with gauze strips and gut explored. A perforation of the small intestine, reaching across the gut nearly to

* Read at a meeting of the New England Pediatric Society held December 4, 1914.

the mesentery was found. This was closed with No. 1 chromic catgut stitches and reinforced with a second layer of the same. The abdominal cavity was then thoroughly washed out with Tait tube and about 25 liters of salt solution. A cigarette wick was placed to the left flank and another to the pelvis. Abdominal wall was closed in layers with chromic catgut, reinforced by through-and-through sutures of silkwormgut. Patient sent to Ward H in poor condition. Stomach washed before patient was out of ether; considerable greenish fluid removed.

July 20th. Patient vomited during night once. Pulse has started to drop, but temperature is up. Patient looks very sick. Getting tap water by rectum and stimulation in form of caffeine and camphor. Vomited once today.

July 22d. Pulse has steadily come down. Patient looks brighter this morning. Getting milk and lime water. Has not vomited since last note.

July 25th. Patient much brighter. Taking fluids in good amounts. Rectal tap water omitted. Wound septic about all stitches. A corset of adhesive plaster with hooks made and applied to keep wound together in case stitches slough out. Considerable foul discharge.

From this time on the patient made an uninterrupted recovery. There was considerable sloughing of the wound which closed by granulation. On September 2d he was discharged in excellent condition, with the wound healed, wearing an abdominal belt. Bowels acting normally.

CASE 2. C. E. A. No 177456. Age eight. Recommended by Dr. J. E. Connelly, of Brookline.

Entered hospital July 27, 1911.

Brought to Accident Room in Brookline Police Ambulance at 12.55 P. M. About one-half hour before entrance was struck by an automobile in front of his home in Brookline.

Examination: Well developed and nourished, little boy, pale, frightened, restless and crying with pain. No evidence of injury to head, chest or upper extremities. There are several slight abrasions on skin of abdomen on left side. Abdomen is held with board-like rigidity, and pressure on it anywhere causes patient to cry out in pain. Tympanitic except in left flank, where there is dullness which does not shift. Liver dullness not obliterated. Over outer side of left thigh is a small lacerated wound.

Patient remained in bed in Accident Room for about one and one-half hours awaiting consent of parents to operation. Was catheterized and small amount of pale urine obtained. Patient seemed to grow steadily paler. He lay quietly in bed and wanted to be left alone. Pulse 140, fair quality. Temperature 98, white cells 39,000. The board-like rigidity of the abdomen, with the rising pulse, high white count and shock, together with the nature of the accident, indicated internal injury with hemorrhage, and immediate operation was advised.

Operation: Septic Room. Ether. Five-inch median suprapubic incision. On opening peritoneum there was a gush of fresh blood, whole cavity was filled with it. Partially swabbed out. Careful inspection of liver and spleen revealed no injury, or source of bleeding. A presenting loop of small intestine was found completely severed, and the mesentery torn. Clamps placed on either side of torn intestine, edges trimmed and brought together in an end-to-end anastomosis with Connell stitch

of Pagenstecher, peritoneal coat united with continuous Lembert stitch. Another loop found where the peritoneum was lacerated completely around the gut, the muscular layer being uninjured. Torn peritoneal edges approximated with continuous Pagenstecher. Inspection of the rest of the intestines, which was very hurried on account of the patient's poor condition, revealed no further injury. Abdominal cavity washed out with hot salt solution. One cigarette wick to pelvis. Wound closed to wick in routine manner in layers. Sent to Ward F in poor condition. Stimulated, shock enema, put in Fowler's position. Given rectal seepage and frequent doses of strychnia.

Patient rallied well. Profuse serous discharge from wick. Unable to retain anything in stomach but water for three days. Bowels moved satisfactorily with enemata. In removing the wick on August 6th under gas a portion of omentum and two coils of intestine were pulled out. Replaced without any ill consequences.

Discharged August 20th in good condition. Wound a small granulating spot. Eating well. Bowels O. K. Walking about ward.

These two cases illustrate the well-known fact that operations for ruptured viscera to be successful must be prompt. In the first case reported, the margin of time elapsed since the accident had very nearly reached the limit of possible successful issue for that particular case. To wait until the diagnosis is certain in these cases is to court disaster. In cases of ruptured intestine, with effusion of septic contents, I feel sure that profuse and thorough irrigation of the peritoneal cavity is a life-saving measure. There has been no time for walling off on the part of nature and hence there need be no fear of spreading the infection; it is an entirely different proposition from a peritonitis from an appendix, in which cases nature has practically always had some opportunity of localizing the process, and irrigation is to be condemned.

I have found that children and adults retain ordinary tap water by rectum as well, if not better, than normal salt solution. Why this should be so, I do not know.

URINARY ACIDITY AND BETA-OXYBUTYRIC ACID DETERMINATIONS IN RECURRENT VOMITING.*

BY WILLARD S. PARKER, M.D., BOSTON.

A. H. 7 years old, had a negative family history. She weighed 6 pounds at birth, was never breast fed but given condensed milk. She gained very slowly the first year. At 4½ months she had an attack of vomiting lasting 3 days. At one year a similar attack. Since then she has had 2 attacks each year until 1911 when she had 6 attacks, with an interval between of 6 to 8 weeks. She had already had several attacks in 1912 when seen in November of that year.

* Read at a meeting of the New England Pediatric Society held December 4, 1914.

She had always been very constipated and has had almost no natural movements since birth, receiving an enema or cathartic almost daily. The stools were always hard and at times contained much mucus. On one occasion she passed a string of mucus 1½ feet long. There has never been any diarrhea nor were the stools ever white or clay colored. The diet had been a very reasonable one, containing little milk or cream but at times considerable butter. The feeding of fat seemed to precipitate some of the attacks. The mother thought the child nervous; she was very active.

A typical attack was as follows:—The child first complained of her throat being sore, though no evidences of inflammation were ever discovered. At this time she was usually slightly yellow. After several hours the sore throat disappeared, vomiting came on and lasted from 3 to 6 days. She was nearly always very constipated just before an attack and the bowels were made to move with great difficulty. The physical examination was as follows:—Flesh firm, color good, weight 42 pounds, about 6 pounds below normal. There was no other abnormality except that the abdomen was slightly distended and the liver enlarged; the liver dullness extended to the upper border of the fifth rib, the edge was felt 5 cm. below the costal margin.

The urine was normal and had a specific gravity of 1010.

The stool showed a moderate excess of fat as soaps.

The Roentgen examination of stomach and intestines was as follows:

The first plate two hours after the bismuth meal showed a dilated stomach reaching to the top of the sacrum. The second plate 6¾ hours after the bismuth meal showed the bismuth in the ileum, jejunum, and cecum. Normally, all the bismuth should have reached the cecum by this time. The third plate, 30 hours after the meal showed, in spite of an enema having been given, a large mass of bismuth in the cecum, some in the transverse and descending colons and in the sigmoid. Normally, there should be no bismuth in the cecum at this time.

Bismuth Enema. The bismuth travelled to the junction of the ascending and transverse colon where it stopped short. At this point there was considerable dilatation, as there was also at the cecum which was distended with gas. Normally, the bismuth should fill the cecum.

The conclusion from these findings was that there was some degree of obstruction in the region of the cecum. That the attacks of vomiting depended wholly, or in part at least, on this condition seemed probable.

The child was put on a rational diet for observation. About one week later she had a severe attack lasting four days, during which she vomited from eight to fifteen times daily. The bowels were moved with difficulty. The abdomen showed for three days considerable masses of fecal material in the right lower quadrant. As soon as enemas and cathartics succeeded in evacuating these masses the vomiting almost immediately ceased. Sodium bicarbonate was given in doses of five grams in twenty-four hours.

Very little of the sodium bicarbonate given by mouth during the attack was retained so it was given by rectum, 2 drams in eight ounces of water three times in 24 hours. Only a part of this was

retained and as the urine remained acid until near the end of the attack, it apparently was not rapidly absorbed. Water, orange juice and cracked ice were given by mouth. The vomiting ceased on the fifth day of the attack.

The following are the urinary findings:

Day of Attack.	24-hour Amount, cc.	Spec. Gravity.	Reaction to Litmus.	H + 10-7.*	Titratable, N/10 Acid	NH ₃ Grams Nitrogen.	NH ₃ N/10	Acid + Alk.	Alk. Given, Gms.	Aceton and Diacetic.	B-Oxybutyric Acid Per Cent.	Gms.
1	360	1021	Acid	5.7	307.	.640	460	767	5.0	+	1.5	5.4
2	530	1022	Acid	5.1	372.	.794	567	937	8.5	+	1.7	9.0
3	620	1024	Acid	5.3	52.	.757	541	593	4.5	+	1.7	10.5

6	510	1016	Acid	8.3	Alk.							5.0
7	950	1014	Alk.	8.3	28.				0.0	0	0.0	0.0

Hydrogen-ion concentration by the Palmer-Henderson Method.
Ammonia by the Folin Method.
Beta-Oxybutyric acid by polariscope.

The presence of the acetone bodies in large amounts, the high acidity of the urine and increased ammonia excretion are all evidence of a true acidosis. The increased ammonia is the reaction usually observed in acidosis and represents the normal reaction of the body to carry off the acids by combination with alkali; the specific gravities in this case are not so high as those frequently observed in the severe cases. The B-oxybutyric acid output is somewhat greater than the amounts found by other observers but there are very few observations on record. Vergeley found 6.8 gms. and 8.5 gms. to the litre. This acid has been found by animal experimentation to be the most toxic of the acid

bodies and there is no doubt clinically that the severest cases are those in which are found the less oxidized bodies, that is, diacetic and B-oxybutyric acids.

A review of the recent literature shows the etiology of the so-called primary acidoses still undiscovered. It is of interest that Sedgewick has found the creatin and creatinin of the urine increased before and during the attacks and that Underhill and Steele found in one case a large amount of lactic acid. Mellamby found an increase in creatinin, and also produced acetonuria in a child subject to recurrent vomiting by sudden withdrawal of carbohydrate from the diet and caused its disappearance by feeding glucose.

Clinically Coomby has noted the frequent connection of recurrent vomiting and chronic appendicitis, while Kerley has called attention to the frequency with which adenoids are found in these cases and the relief often obtained from operation. He has also noted that recurrent bronchitis is a condition which often occurs in children subject to recurrent vomiting and that the attacks may be simultaneous.

In the case here reported laparotomy was done. No adhesions were found. There was a general visceroptosis, dilated stomach and cecum. The cecum was so dilated that it was thought best to infold it. The appendix was removed. The child had no more attacks for ten months. The attacks then recurred but not with their former frequency and severity and there have been in the last year only a few very mild attacks. The vomiting would seem then to have been due in large part to the intestinal condition, so we have in this case though a secondary acidosis, a very severe one, and the suggestion is that more of the cases of recurrent vomiting be subjected to roentgen examination of the gastro-intestinal tract.

THE SIGNIFICANCE OF X-RAY EXAMINATION FOLLOWING OPERATION FOR CONGENITAL PYLORIC TUMOR.*

By CHARLES L. SCUDDER, M.D., BOSTON.

Surgeon to the Massachusetts General Hospital; Associate in Surgery, Harvard Medical School, Boston.

Cases of congenital stenosis of the pylorus may be grouped into four classes:

*Read at a meeting of the New England Pediatric Society, December 4, 1914.

The first class includes all those cases which died previous to the date of the recognition of the condition by medical men. All those cases were treated medically and were experimentally fed. They all died.

The second class includes those cases which have been unrecognized dating since the time this disease has been understood and carefully studied. All these cases have been medically treated and have died.

The third class includes those cases which are recognized by the attending physician as cases of congenital stenosis of the pylorus, are referred to the surgeon for treatment, are operated upon and die. These cases usually die of starvation because of delay in instituting adequate treatment.

The fourth class includes all those cases which are recognized by the physician, are referred to the surgeon for operation, are operated upon and recover.

The chief difficulty which physicians and surgeons have in dealing with these cases of congenital stenosis of the pylorus is in making a positive diagnosis. One thing which makes the diagnosis difficult is the assumption on the part of the physician that pyloric spasm plays any part in tumor stenosis. I believe that pyloric spasm has nothing whatever to do with the condition of congenital stenosis of the pylorus. All variations in the degree of stenosis and the behavior of cases subsequently proved to be tumor cases may be explained without the assumption of pyloric spasm.

In these cases of congenital pyloric stenosis obstruction at the outlet of the stomach is the important fact. That obstruction in general at the pylorus may be either mechanical or physiological is generally recognized. But so far as any individual baby is concerned having a pyloric tumor, the obstruction is due to the tumor itself encroaching upon the lumen of the pylorus, and is not dependent in any way upon a spasm of the pyloric muscle. Variations in the degree of stenosis may be explained purely upon mechanical grounds: namely, upon the swelling of the mucosa, upon the encroachment of the tumor upon the lumen of the canal, and of the reduplication of the longitudinal folds of mucous membrane normally within the canal, all of which conditions can be proved to be present, and none of which conditions has to be assumed.

Anatomical variations of this sort are competent to account for that which heretofore has been explained only upon the assumption that tumor obstruction is associated with a pyloric spasm. If we can eliminate the idea of pyloric spasm from this group of tumor cases we shall go a long way toward reaching a quick diagnosis with shorter periods of experimental feeding and consequently such tumor cases will receive proper surgical treatment at an earlier date and the lives of more babies be saved.

Dr. H. M. Richter (personal communication) of Chicago has had 11 cases of congenital stenosis of the pylorus examined by means of the x-ray bismuth meal by Dr. Case of Battle Creek, Michigan. Ten of these 11 cases were tumor cases. In each case there was demonstrated a complete closure of the pylorus and in each case bismuth passed through the stoma and not through the pylorus. These x-ray examinations were made from 7 days to 3½ years following the operation of gastro-enterostomy.

In one case of Richter there was no tumor but a spasm of the pylorus. A posterior gastro-enterostomy was done and after three years had elapsed the x-ray examination showed the bismuth passing both ways, that is, through the pylorus and through the stoma. This is a very significant case compared with the true tumor cases.

Dr. W. A. Downs of New York has had examinations made by the x-ray bismuth meal of 6 cases of congenital stenosis of the pylorus subsequent to operation. Invariably in these 6 cases the bismuth passed through the stoma and none went through the pylorus. The period of time which had elapsed from the operation to the x-ray examination was from four months to two years in these six cases.

Dr. James L. Mitchell of Washington, D. C., reports one case in which a bismuth examination 2½ years after posterior gastro-enterostomy was done for a pyloric tumor. This report showed that no bismuth passed through the pylorus, but that all went through the stoma.

Four years ago in a paper published in *Surgery, Gynecology and Obstetrics** I recorded the interpretation of x-rays taken by Dr. Walter J. Dodd following a bismuth meal in nine of my own cases of congenital stenosis of the pylorus that had had the operation of posterior gastro-enterostomy. These were among the first x-rays to be taken of such cases. In every instance the bismuth meal was seen to pass through the stoma and nothing was seen to pass through the pylorus. These x-ray examinations were made from one to eight years following operation. I am now having a larger series x-rayed.

Here then are well-authenticated reports of an x-ray bismuth examination in 26 cases of proved congenital stenosis of the pylorus following posterior gastro-enterostomy. All of these cases were observed by skilled physicians, surgeons and roentgenologists. The returns from these 26 cases are uniform. In each case the pylorus was obstructed, in each case the stoma was patent and was the only exit for the bismuth meal from the stomach. From this evidence it is fair to conclude that the tumor seen at operation continues to obstruct the pylorus.

In this connection it is important to recall the classical case of Morse-F. T. Murphy-Wolbach, of a child who had a congenital pyloric tumor obstructing the pylorus, in which a posterior gastro-enterostomy was done. The child died

seven months subsequently from a cause unconnected with the stomach. At the autopsy the tumor seen at operation was found unchanged.

To this original observation may be added the case of Grulee and Lewis of Chicago. (Personal communication. To be reported by Dr. Lewis in detail in the *Jour. of the A. M. A.*) The child was operated upon shortly after birth because of a pyloric tumor. Nine months later the baby died of pneumonia. At the autopsy the tumor was found to be present blocking the lumen of the pylorus. To this report may also be added the record of Case 14 in Dr. Downs series. This child, Case 14, died of diphtheria three and one-half months after posterior gastro-enterostomy for a tumor of the pylorus. The tumor in this case was of the same size as at operation and was still obstructing the pylorus.

There are, therefore, three authentic cases in which the pylorus tumor discovered at operation has been seen from three to nine months following a plastic operation. These facts taken with the postoperative x-ray findings in the 26 cases recorded above afford a reasonable basis for the conclusion that the pyloric tumor persists and does not tend to disappear. The recognition of the persistence of the tumor in congenital pyloric stenosis is important.

a. The tumor alone with the mucous membrane changes is an adequate cause of the obstruction in all its phases, and it is unnecessary to imagine a pyloric spasm associated with the obstructing tumor.

b. The surgical treatment of these cases is without any question the only permanently effective treatment.

c. The postponement of the operation with the idea, now so prevalent, that the hypothetical spasm will let up and the tumor disappear and the child recover is unjustifiable.

d. A baby having tumor obstruction will always have tumor obstruction.

e. The omission of the hypothetical pyloric spasm from any consideration in these cases will result in earlier adequate surgical relief.

SOME STUDIES IN FAT INDIGESTION.*

BY CHARLES HUNTER DUNN, M.D., BOSTON.

Abstract: The cases studied at the Infants' Hospital were those which showed a marked intolerance of cows' milk fat, manifesting itself by showing signs either of failure of fat absorption, or of failure of digestion, or of both. These cases showed a variety of clinical features, the chief sign of intolerance being the appearance of excessive fat in the stools. The typical feature of fat indigestion is summarized in these words: Inability to gain weight without fat, and inability to gain with it.

* Read at a meeting of the New England Pediatric Society held December 4, 1914.

The points studied, and the conclusions reached, were the following:—

1. Are there any striking predisposing causes for fat indigestion? Chronic disease, particularly tuberculosis, was found associated with these cases with marked frequency. In the study of previous feeding, overfeeding with carbohydrate was found to be the history, rather than overfeeding with fat. The effect of long continued overfeeding and its consequent fermentation may be the primary injury, causing a failure in the power of digesting fat, which later comes to dominate the picture.

2. Can we successfully compensate for deficient power to digest and absorb fat, by increasing carbohydrate or protein, and if so, to what extent? The answer to this question is, to a very slight extent. The three elements, fat, sugar, and protein, must bear a fairly constant proportion one to another.

3. Is the micro-chemical examination of the stools for fat a reliable guide to the feeding of these cases, and if so, to what extent? The conclusion was that it is indispensable for the proper management of these cases. Nevertheless, the continued presence of excessive fat or soap in the stools is not incompatible with prolonged gain in the weight and freedom from clinical symptoms of indigestion. There is always some danger, where excessive fat is present, of a sudden "blow up," with clinical symptoms and rapid loss of weight. Free fat is always a danger sign.

4. What are the relative values of maltose and lactose as the carbohydrate element in these cases? In general, babies who cannot gain weight on a certain percentage of fat with lactose, can gain better on the same percentage of fat when maltose is substituted. As to whether the use of maltose actually increases the power of digesting and absorbing fat, the evidence is contradictory, and not conclusive.

5. What are the relative values of precipitated casein, and unmodified protein in these cases? This point is interesting in connection with the theories of the possible rôle of the cow's salts in fat indigestion. The evidence was contradictory and not conclusive. Fat "blow ups" occurred with the same quantity of fat, in cases where both forms of protein were successively used. Some cases did better with precipitated casein, but in no case did its use show clear evidence of increasing the power of digesting and absorbing fat. The gain appeared to come from the fact that in some cases precipitated casein is better digested than unmodified protein.

6. What is the value of lactic acid milk in these cases? The evidence on this point was not sufficient to permit the drawing of any conclusions.

The following is a summary of the ideas now held at the Infants' Hospital as to the treatment of these severe cases of fat indigestion.

The milk modifications used must be low in

fat, average in carbohydrate, comparatively high in protein. The extra sugar should be maltose. A certain number of the milder cases will do well on this treatment. Severe resistant cases are those which cannot gain on a low quantity of fat, and cannot tolerate an increase. A large number of cases are so severe and resistant that they can only be saved by human milk. Breast milk will save most of these cases, even the severe ones, if used in time. It should always be used in resistant cases, whenever it can be obtained. Even a little breast milk is of value and may save a case which would otherwise be fatal. After a period of breast milk feeding, many cases are found no longer severe and resistant to artificial feeding. If breast milk cannot be obtained, the feeding is very difficult and the outcome uncertain. Excessive increase of carbohydrate or protein will not help these severe cases, and may do harm; I do not believe more than 7% carbohydrate, or 3% protein, should be given. Whey mixtures are of no help, except sometimes in very young babies, who vomit curds; they may do harm. Giving the protein in the form of precipitated casein may be tried, and may help in some cases. There is not sufficient evidence of its value to indicate its use as a routine.

The only way we have of managing these resistant cases without breast milk, is to keep the fat low, and we must be prepared for a period of loss of body weight, which may be prolonged. If they begin to gain when the fat is increased, it is no sign of permanent improvement; they may go to pieces at any time. Frequent examination of the stools for free fat and excessive soap must be made. In the presence of free fat, or in the continuous or increasing presence of excessive soap, the fat should be reduced, even if the baby is gaining. If a "blow up" occurs when the fat is increased, the fat in the food should be reduced to zero, and then worked up again, slowly. Frequent "blow ups" diminish the tolerance of fat. The best hope of eventually obtaining an increase in tolerance of fat sufficient to permit a gain in weight, is to avoid overfeeding with fat for a long time, even if much weight is lost.

ACUTE AND CHRONIC EMPYEMA.

AT THE MASSACHUSETTS GENERAL HOSPITAL
DURING A PERIOD OF TEN YEARS FROM JAN-
UARY 1, 1901, to JANUARY 1, 1911.

BY WYMAN WHITTEMORE, M.D., F.A.C.S., BOSTON,

*Surgeon to Out-Patients, Massachusetts General Hos-
pital; Assistant in Surgery, Harvard Medical School.*

I HAVE looked up and traced, as far as possible, the end results of the cases of acute and chronic empyema operated on at the Massachu-

setts General Hospital during the period of ten years from January 1, 1901, to January 1, 1911.

I realize that statistics may not be of any great importance or especially interesting, but they are of a certain value if they bring out facts that have not been realized before, and perhaps make it possible for better surgery to be done.

There has been a high mortality in the acute cases and a good many of them have become chronic. In going over the records of some 269 cases, and seeing many of those who return in answer to letters sent to them, I have tried especially to find out why the mortality was so high and how it might be reduced.

During this period of ten years there were 269 cases of acute empyema operated on. I have traced the end results in 154 of these. The remaining 115 cases I have been unable to trace; letters have been sent to the patients, then to family doctors, and finally to town clerks, but without success. A large number of patients were foreigners and they have probably drifted to other towns.

Out of the 154 cases that have been traced, there were 54 that died following operation, giving a mortality of 20%. One hundred cases left the hospital alive; 68 are well at the present time. By this I mean that there is no discharging sinus, no bad effects from the operation, and they are able to attend to their regular occupation. Twenty have become chronic. These have a persistent sinus and a cavity with a much thickened pleura, as a rule. The remaining 12 have died since leaving the hospital: one died from an accident, one from diphtheria, three from kidney disease, one from tuberculosis, one from scarlet fever, one from meningitis, one from heart disease; in three cases the cause of death is not known. There has been, apparently, no connection between the cause of death and their empyema.

An autopsy was performed on 30 of the cases that died following operation: 14 died from septicemia, five from pneumonia, three from pyemia, one from peritonitis, two from multiple abscesses of the lung, one from defective closure of the foramen ovale and thrombosis of the left pulmonary artery, in four no definite cause was found. The commonest cause of death was septicemia; the majority being streptococcus septicemia and a few pneumococcus septicemia. I cannot report on any definite cause in the other 24 as there were no autopsies performed on these.

There were 35 cases of chronic empyema operated on during this period of ten years. I have traced the end results in 23: 15 are entirely well; four did not improve by operation, that is to say they have a persistent sinus and are practically chronic invalids; two cases died following operation; two cases have died since leaving the hospital, cause of death not known. Of the two cases that died in the hospital, one had an autopsy performed, the cause of death being

adenocarcinoma of the main bronchus and extensive bronchiectasis.

END RESULTS OF OPERATIONS FOR CHRONIC EMPYEMA.

	Number of Cases.	Well.	Not Well.	Died Following Operation.	Mortality.	Died at Home.	Not Traced.
Decortication of lung	5	3	1	1	20%		
Excision of ribs							
Pleura curetted	21	7	2	1	5%	2	9
Excision of ribs							
Parietal pleura excised	4	2					2
Sinus explored, curetted, etc	3	3					
Excision of ribs							
New cavity drained	1		1				
Excision of ribs							
Old drainage tube removed	1						1
	35	16	4	2		2	12

Many of the cases were desperately sick when they reached the surgeon, having had a severe pneumonia.

I feel that the cause of many of the bad results was that the diagnosis was not made early enough and that the operation was not done soon enough. The earlier the diagnosis and the earlier the operation the better. I believe that one should operate when aspiration shows the serum to have a good many leucocytes in it rather than wait until it becomes pus.

A good many cases are not drained at the bottom of the cavity so that there is a certain collection of pus that does not drain easily. If in exploring a cavity through the first incision one is not at the bottom, I believe a second incision should be made, provided the patient's condition allows it.

Clinical Department.

REPORT OF A CASE OF CONGENITAL MULTIPLE CYSTIC DISEASE OF THE KIDNEYS IN WHICH ONE KIDNEY WAS REMOVED.

BY FRANCIS S. WATSON, M.D., BOSTON.

THE case of the patient which is here reported is thought worthy to be published because of the fact that the conditions existing in the kidney which determined its removal were somewhat exceptional, though by no means unknown, and because the patient having multiple cystic disease of the second kidney nevertheless has lived for six and a half years since the operation and has been well enough to work during the larger part of that time.

The patient, a young man twenty-five years of age, was admitted to the surgical service of the Boston

City Hospital in March, 1908, having been attacked four days previously while being in good health so far as he was aware, with severe pain in the left loin and left upper quadrant of the abdomen.

He had vomited once or twice at the onset of the pain but not since. When admitted his temperature was 100.5°, pulse 90, full and regular, tongue coated. He was feeling weak and somewhat exhausted, was pale of complexion, and looked a sick man. Physical examination was negative except with regard to the right side of the abdomen. On this side the abdominal muscles were tense, and there was a decided sense of resistance to palpation. A tumor of large size could be felt occupying the right renal region and extending forward and downward to the border of the ilium. It presented the usual characteristics of a renal tumor. Cystoscope and ureteral catheterization showed the bladder to be normal. The urine drawn from the left ureter showed distinct differences from that which was obtained from the right one. Urine from left kidney had a sp. gr. of 1009, was pale in color, contained a good deal of pus and a considerable amount of microscopic blood. Albumen in larger quantities than would correspond merely to the blood present. No abnormal renal elements: casts or renal epithelium, or crystals, etc., were found. Urea diminished. The urine from the right kidney had a sp. gr. of 1018, was of normal color, and showed a faint trace of albumen. Urea normal in quantity, color normal, solid constituents practically normal, no pus, an occasional hyaline cast. The last named, and the trace of albumen were the only abnormal elements present in the urine from that kidney. The right kidney was palpable and found to be larger than normal, however.

There was no tenderness on pressure over the right kidney or tension of the abdominal muscles, as on the left side of the abdomen.

There was no history suggestive of renal calculus, other than the present attack, but radiographs were taken of both kidneys and ureters, which failed to show the presence of calculus.

Diagnosis. Long-standing hydronephrosis with recently supervening infection of the left kidney and its conversion to pyonephrosis.

Operation. March 30, 1908. The left kidney was exposed by the lumbar incision parallel with the outer border of the quadratus lumborum muscle. This incision was extended later by a transverse cut from its upper end in order to permit the removal of the very large kidney which was found to be present.

The kidney was seen to be the seat of polycystic disease. It was about 22 cm. in length and ten cm. in width. A considerable number of the cysts within view were distended with blood, there were two areas of suppuration visible and in two other parts of the organ's surface a process of gangrene was beginning.

It was felt that the patient's life would be sacrificed if the kidney were allowed to remain, and despite the great probability that the second kidney was involved in the same condition of cystic disease, it was decided to remove the one that had been exposed.

The organ was too large to allow of its being taken out entire, and it was necessary to resect a part of it before this could be done. After being removed, another and larger area of gangrene was revealed nearer the upper pole of the organ, and on

cutting the kidney in two a cavity filled with pus and of the size of a turkey's egg was laid open.

Further examination showed that there were two or three of the branches of the renal vein which were plugged by thrombi. The condition of the organ made evident the wisdom of the decision to remove it.

The patient made a rather slow but excellent recovery. Shortly after leaving the hospital the urine from the right or remaining kidney was free from pus and showed only the abnormal elements in the urine that have been mentioned above. The patient has been seen by the writer on four or five occasions since, the last of which was a few days since on Nov. 23, 1914, or six years and nearly eight months after the operation. Despite the fact that the urine now contains pus, is of low specific gravity and has a rather large percentage of albumin, the man's general condition has been progressively better during the past year than at any previous time after the operation. He says, however, that he feels very weak and that during the past four months or so he has had rather frequent recurrent vomiting and loses his appetite and strength entirely during these times; between these attacks he has a good appetite and says he digests his food apparently very well.

The case seemed to the writer to present certain features of interest, chief among them, that while it is always regarded as a grave mistake to remove a polycystic kidney under ordinary conditions, because of the great probability of the actual presence of, or soon to be developed, disease of the same character in its fellow organ of the opposite side, yet there are conditions which may exist in one of the kidneys which so greatly imperil life at a given moment that there is far greater danger in leaving the kidney in which they exist in the body than in taking it out. The chance of prolonging the life of the patient to an important degree under these conditions will be indicated or its contrary be suggested by the evidence of good or poor functional condition of the kidney of the other side at the time when the question of nephrectomy arises. If that kidney is shown to be seriously involved already, it is, of course, obvious that it would be of little or no avail to remove its fellow organ, no matter if its condition was such as to immediately endanger life were it allowed to remain. If, on the other hand, the urinary examinations show that the functional condition of the kidney that is to remain after the operation is still capable, it would be a mistake not to remove its fellow under such conditions as were found in the case here reported.

The other point that is of interest is that a patient in whom the second kidney, that is to say, the one that is not to be operated upon, is functionally good at the time the operation is contemplated, the patient may very probably secure a fairly long term of life, after the nephrectomy and will have his life saved from the danger that is at the time imminent. Moreover, there are a few exceptional cases in which the disease is and remains unilateral, and in these

there is no reason why the patient should not after being freed from the danger threatened to life by the conditions in the kidney that is involved in the disease called polycystic, live as long as most people do following the removal of the affected kidney.

When therefore a polycystic kidney is found to present such conditions as those found in this case, namely, areas of gangrene, and collections of pus, whether the cystic condition be very far advanced or not, it should be removed unless the urinary examinations of the product of the opposite kidney indicate that it, too, is too far involved in the cystic process to give a period of life afterward that is not sufficiently important to be considered. Then only would one refrain from doing a nephrectomy on its mate.

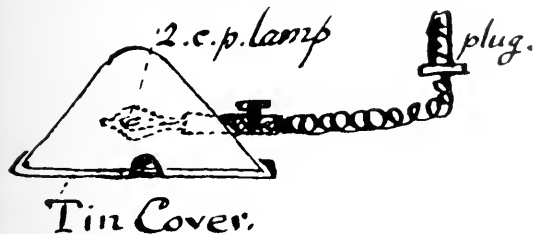

New Instrument

A CHEAP ELECTRIC HEATER.

BY EDWARD VON ADELUNG, M.D., OAKLAND, CAL.

THE following device has been used as a substitute for a rubber hot-water bag for over two years, and has proven more effective, more convenient, and cheaper. So much so that I have decided to put it into print.

The outfit consists of a two-candle power carbon filament lamp in an ordinary metal, scoop-like reflector (as sold in all electric stores), with sufficient cord and a plug to connect with a convenient fixture. The reflector is converted into a metal box by a sheet of tin which is cut the proper size to close the open side of the reflector, leaving small ears to be bent over to hold the tin on. To prevent the metal from coming in contact with the skin, the box is slipped into a flannel or cotton bag with a draw-string. The arrangement is made clear by the sketch.

A sixteen candle-power lamp burning twenty-four hours in this box will not light bed clothes, —nor even paper. So that with a two candle-power lamp there is absolutely no danger of fire. Still such a small lamp yields all the heat that one can stand.

Many of my patients find the device a very great comfort. The ease with which one can use it without getting out of bed renders it especially

convenient, and gives it a great advantage over the rubber bag. It cannot leak. In sickness it is superior to the water bag or bottle because it maintains its temperature, and is not heavy. When placed over cloths rung out of hot water, and the whole covered with flannel, a poultice is obtained superior to the ordinary poultice, and not requiring renewal. Its many applications in health and in sickness suggest themselves.

Any electric house can put the parts together at a cost not over two dollars. The amount of current used is very small, and the cost of maintenance is practically zero.

Medical Progress.

THE BACTERIOLOGY OF THE GASTRO-INTESTINAL CANAL IN INFANCY. A SUMMARY.¹

BY JOHN LOVETT MORSE, M.D., BOSTON.

AND

FRITZ B. TALBOT, M.D., BOSTON.

BACTERIOLOGY OF THE MOUTH.

THE infant's mouth is sterile before birth, but becomes infected from the mother's vagina during birth² or from the air soon after birth.³ The variety of organisms present at this time is relatively small, but as soon as the infant commences to take food the flora becomes more complicated. The number of bacteria does not, however, increase. When the infant takes breast milk, there is an increase in the variety of the organisms, and pathological bacteria may even be found in the mouths of healthy babies.⁴ Because of the fact that even the purest cow's milk contains more bacteria than human milk it is reasonable to expect that the mouths of babies fed on the bottle will contain a greater variety of bacteria than the mouths of those fed at the breast, and that the dirtier the milk the greater will be the variety of the organisms. There are, however, no data as to whether this is true or not.

After the eruption of teeth, *i.e.* after the infant is six months old, the number and variety of the bacteria increase,⁵ and certain micro-organisms, such as the *Leptothrix*⁶ and fusiform bacteria,⁷ which are apparently only able to obtain a foothold in the mouth when teeth are present,⁸ appear.

It is an open question as to how important a part the bacteria of the mouth play in the digestion processes in the stomach. It is conceivable that these bacteria, especially when there is dental caries, may do harm. It has not been proven, however, that they do.

BACTERIOLOGY OF THE STOMACH.

The same influences which modify the bacterial flora of the mouth naturally modify that of the stomach. Under physiological conditions the bacteria in the stomach play an unimportant rôle. A description of the individual kinds may be found in the works of Escherich,⁹ who was a pioneer in this field of investigation. The smallest numbers are found in the stomachs of the breast-fed,¹⁰ and they remain relatively scarce as long as the digestion is normal. When there is indigestion, there is an increase in their numbers. The greatest numbers are found in cholera infantum.¹¹

Bactericidal Powers of the Stomach. There is no doubt that free hydrochloric acid is able to destroy bacteria in the stomach,¹² but this action is prevented to a greater or less extent by the fact that the hydrochloric acid is strongly attracted by the proteins of the food and quickly combines with them, thus becoming inert. Furthermore, since the casein in the milk is rapidly coagulated into curds, the disinfecting action of the hydrochloric acid can only be effective on the surface of the curds, and the large numbers of bacteria which are present in the interior of the curds are not reached by it.¹³ The number of bacteria in the stomach apparently depends also on the activity of the gastric motility, for the quicker the stomach is emptied, the fewer are the bacteria which it contains. The converse is also true.

Lactic acid fermentation does not seem to play as important a part in the stomach of the infant as it does in the adult, in whom it occurs only when hydrochloric acid is absent. Lactic acid is seldom or never found in the stomach of the breast-fed, but is frequently found in small amounts in the stomach of infants fed on cows' milk.¹³

Butyric acid fermentation is more common¹⁴ and has been found to occur in the stomachs of atrophic infants in which the secretion of hydrochloric acid and the motility are both diminished. The pasteurization or boiling of milk destroys the organisms which produce lactic acid, but does not kill the spore-bearing bacilli which produce butyric acid. The latter cause the formation of butyric acid from carbohydrates and fat and possibly from protein. Whether butyric acid is formed or not depends, according to Tobler, not on the kind of food present, but on the type of bacteria. This may be in part true, because fermentation cannot take place without fermentative organisms. On the other, however, the food components necessary for fermentation must be present in sufficient quantity to supply the bacteria with fermentable material. The lactic acid bacilli and the butyric acid bacilli are the only organisms which usually play a part in the various processes of acid production in the stomach. The other bacteria which form acid are usually found only in the lower intestinal canal.

BACTERIOLOGY OF THE UPPER PART OF THE SMALL INTESTINE.

The upper part of the small intestine, in comparison with the rest of the digestive canal, is relatively free from bacteria, both in the breast and in the bottle-fed infant. Hess¹⁵ studied the bacteria of the duodenum during life by an ingeniously devised modification of his duodenal catheter. He found that in new-born infants, who had received no food, the duodenum contained very few organisms, only from one to three growing on a plate. The organisms were staphylococci, gram-positive and gram-negative bacilli. Colon bacilli were not found. Infants in the first week of life also had very few bacteria in the duodenum and these were of the same varieties as those found soon after birth. There was more or less similarity between the bacteria of the stomach and the duodenum. The staphylococcus was the organism most frequently found at this age. Hess could not establish any relation between the amount of hydrochloric acid in the stomach, or of bile in the duodenum, and the number of bacteria. The presence or absence of icterus made no difference in the bacteriology of the duodenum in these babies. Cultures from the duodenal contents of older breast-fed babies showed from one hundred to two hundred colonies per plate. Those from bottle-fed infants showed many more.¹⁶

There is evidence that, while the duodenum may be practically free from bacteria during the intervals between digestion, there is a relatively large population in the small intestine while the food is passing through it.¹⁷ According to Ficker¹⁸ and Moro¹⁹ the flora of the upper small intestine is composed principally of short gram-negative rods (colon bacillus and bacillus lactis aerogenes) with an occasional isolated bacillus bifidus communis, bacillus acidophilus and butyric acid bacillus, and enterococci.

Under pathological conditions there may be an enormous increase in the bacteria in the small intestine. Prolonged fasts are regularly followed by an increase in the number of bacteria,¹⁸ while all processes which cause an inflammation of the mucous membrane of the small intestine result in a diminution of its protective action against bacteria and a consequent increase in their numbers.

Moro²⁰ believes that there can be an endogenous infection of the small intestine. Such an infection is probably present in most disturbances of nutrition, both acute and chronic. The epidemic of severe diarrhea, associated with the presence of inflammatory products in the stools (blood and pus), described by Escherich,²¹ has been used as evidence for this point of view. The infants attacked were all young, their ages varying between four and ten months. The stools contained bacteria which were proved to be, almost without question, "aciduric"²² or acidophilic organisms. These organisms were probably identical with those which are normally

present among the flora of the healthy nursing. Logan,²³ on the other hand, was unable to show that any colon-like organisms from cases with diarrhea showed any greater virulence to guinea-pigs than the same organisms from babies not suffering from diarrhea.

BACTERIOLOGY OF THE LOWER PART OF THE SMALL INTESTINE AND OF THE LARGE INTESTINE.

There are relatively few bacteria in the healthy small intestine down to the lower part of the ileum. There they begin to increase in number, so that when the large intestine is reached they are very numerous. The types of bacteria which are commonly found, according to Kendall, are as follows²²: The more commonly recognized bacteria are the *B. bifidus* of Tissier, the *Mic. ovalis*, the *B. coli*, the *Bact. aerogenes*, and the *B. acidophilus* (Moro). These make up the normal nursing fecal flora. The *Bact. lactis aerogenes* appears in the upper levels of the tract, that is, the duodenum and jejunum; the *Mic. ovalis* in the lower jejunum and in the ileum to the ileo-cecal valve; the *B. coli* and the *B. acidophilus* in the region of the ileo-cecal valve, while the *B. bifidus* appears to dominate the ascending and transverse colon. This cannot be accepted without reservation since intestinal bacteriology is by no means so simple as it would appear from the foregoing statement. The remainder of the tract to the anus is relatively poorly populated in relation to the cecum so far as living bacteria are concerned. This is due in part to the considerable degree of desiccation of the fecal contents of the intestines and in part to the accumulation of waste products, which appear to inhibit the development of bacteria.

The character of the bacteria in the large intestine depends largely upon the food,¹⁹ and, since human milk is a relatively homogeneous food, the tendency of the bacteriological flora of the breast-fed is toward uniformity. The bacteriological conditions in the artificially-fed are, as would be expected, less consistent, because there is no uniformity in the food which they receive. The distinctive features of the stools of the artificially-fed are the relative increase of gram-negative bacilli of the colon-aerogenes type and of coccal forms of the *Mic. ovalis* type. Coincidentally, there is a decrease in the number of organisms of the *B. bifidus* type. The *B. acidophilus* is relatively more numerous and the *B. bifidus* less numerous.

BACTERIOLOGY OF THE STOOLS.

The first stools (meconium) of the new-born are sterile, but they become infected shortly after birth. Within eighteen to twenty-four hours after birth, bacteria make their appearance in the stools and the meconium begins to disappear. The kinds and the number of bacteria which are found depend largely upon the season and the environment of the infant.²⁴ This is a period of mixed infection. The following organisms have

been found in meconium: *B. subtilis*, *B. coli*,²¹ *B. bifidus*, *B. putrificus* Bienstock, butyric acid bacillus,¹⁶ and enterococci.²⁵ These organisms undoubtedly gain entrance to the intestinal canal through both the mouth and the anus. Meconium is a poor culture medium, probably because of its small water content.

The *B. bifidus* appears about the beginning of the third day and persists throughout the nursing period. It is an obligate anaerobe (Kendall), gram-positive, and is the most characteristic organism of the nursing's stool. It is apparently independent of the quality of the stool and is present in the classical golden-yellow, homogeneous, pasty stool as well as in those which deviate from this character in consistence and color.¹⁶ Although the *B. bifidus* dominates the typical field, other gram-positive bacteria can always be found. Other bacteria that have been described in the stools of the nursing are cocci, the *B. lactis aerogenes*, the *B. coli*, the *B. acidophilus*, butyric acid bacilli, the *B. mesentericus* and the *B. aerogenes capsulatus* (Welch).

The bacteriology of the stools of the artificially-fed infant is much more complicated than that of the breast-fed. No characteristic type of bacteria predominates, but there is a mixture of bacterial types. Culturally, the same species are found as in the stools of the breast-fed infant. The general picture is, however, apt to be gram-negative in contradistinction to that of the stool of the breast-fed infant, which is usually gram-positive. The *B. coli communis* and the *B. lactis aerogenes* are the most numerous of these predominating gram-negative bacteria. A peptonizing bacillus, which is almost always absent from the stools of the breast-fed, has been recorded by Rodella.²⁶ Passini²⁷ found three types of butyric acid forming organisms, and isolated peptonizing organisms from the stools of apparently normal bottle-fed babies. The *B. putrificus*, the most typical example of a purely proteolytic organism, has been found in several cases.

The discussion as to the causes which influence the appearance and disappearance of certain bacteria is of more than polemic interest, since it may lead to some conclusions which will have a practical application. Kendall's²⁴ view is given as follows: "The intestinal tract is sterile at birth, because the uterine cavity is sterile. The first infection takes place adventitiously. Any organisms which enter by the mouth or through the anus in the bath water, which can exist at body temperature, will find lodgment in the intestinal tract and may temporarily grow there. Many of the bacteria which thus succeed in entering the alimentary canal are spore-forming. During this period the food which is presented to them is largely detritus of fetal origin. At the beginning of the third day, when the breast milk has had a chance thoroughly to permeate the intestinal tract, new organisms appear, organisms which have a definite relationship to the type of food which is presented to them. It

will be remembered that breast milk contains essentially 7% of lactose, about 3% of fat, and but 1½% of protein. Carbohydrate is, therefore, the dominant food. It is noteworthy that the organisms which appear in response to this diet are those whose metabolism is intimately associated with the utilization of sugar. These organisms thrive but poorly in a medium from which sugar is excluded. When other foods begin to replace the breast milk there is a definite change in the types of bacteria represented in the intestinal contents. The obligate fermentative bacteria, such as the *B. bifidus*, are replaced by more plastic forms and the *B. coli*, which can accommodate their metabolism rapidly to dietary alterations. The *B. coli*, for example, can thrive equally well on a medium in which carbohydrate is absent. It might appear from this rather definite alteration of types of bacteria in the intestinal tract following changes in the character of the food, that the food alone determined the intestinal flora. This may be somewhat influenced by the intestinal secretions. The essential feature, however, is the very direct relationship between food and bacterial response to it. This recognition of a relationship between food and bacteria in the intestinal tract is important in considering the intestinal flora, for it correlates the metabolism of the flora with the effects which it produces rather than attempting to establish indistinct relations between the morphology of the flora and these effects." These conclusions are supported by the work of Sittler,²⁸ and Bahrdt and Beifeld.²⁹

Further investigations are necessary to throw more light on this subject, which is not as simple as it appears. It seems probable that other factors besides the sugar alone may play an important part in determining the intestinal flora, most important of which is the relation of the sugar to the other food components, especially those which favor putrefaction.³⁰

It is interesting to note that Noguchi³¹ in studying the growth and characteristics of the *B. bifidus* was able to transform it in the laboratory from the strictly anaerobic type (*B. bifidus*, Tissier) to the facultative aerobic type (*B. acidophilus*, Moro) and back again to the anaerobic type. Logan²³ believes that the *B. bifidus* of the breast-fed is replaced by the *B. acidophilus* in the bottle-fed.

The Number of Bacteria in the Stools. The most reliable figures as to the bacterial content of infants' stools are those obtained by Strassburger's method.³² He found that the bacterial content of infants' stools was as follows:

TABLE.

AGE.	FOOD.	DIGESTION.	PERCENT. OF DRIED STOOL.
2 months	Cow's milk	Normal	11.5
4½ "	" "	"	42.3
5 "	" "	?	35.2
2 "	Human milk	Normal	25.8
1 "	" "	Dyspeptic	61.4

Leschziner³³ found that 2% to 28.4% of the dried stool of the healthy breast-fed infant was composed of bacteria, while from 6.52% to 29.4% of the total nitrogen was derived from bacteria. The newer and more perfect methods of Kramsztyk³⁴ and Klotz³⁵ show that the number of fecal bacteria varies with the kind of food and that it is the chemical composition of the food rather than its bacterial content which is of significance.

Escherich³⁶ has shown that sterilization of the food has very little or no influence on the number of fecal bacteria.³⁷ Kramsztyk found the smallest number in the stools of infants fed on the breast. He found more in the stools of those fed on diluted cows' milk, and most in the stools of those taking both human and cows' milk. Carbohydrates, especially in the form of malt extract, increase the number of bacteria. Klotz, whose figures are somewhat higher, found that the maximum amount of fecal bacteria in the dried feces is from thirty to thirty-six per cent. He also found the smallest numbers in soap stools. Strassburger, however, found that 60% of the dyspeptic stool was made up of bacteria. Although counting the number of living bacteria is attended with many difficulties, there can be but little doubt that a large proportion of the fecal bacteria are dead.³⁸

Pathogenic Bacteria. The typhoid bacillus and the various types of paratyphoid bacilli may be present in the stools of infants under the same conditions as in adults. The same is true of the tubercle bacillus and the cholera bacillus, as well as of other uncommon micro-organisms, such as the bacillus of anthrax.

The various types of the dysentery bacillus are frequently found in the stools of infants. So also is the gas bacillus, as well as other closely allied micro-organisms. When these organisms are found in considerable numbers in association with the symptoms of disease of the intestinal tract, as in infectious diarrhea, they are, in most instances, the cause of the disease. This is also the case when large numbers of streptococci are found in association with fever and diarrhea. The presence of a few of these organisms in the stools in cases of diarrhea does not prove, however, that they are the cause of the symptoms. They also may sometimes be found in small numbers in the normal stools of apparently healthy infants. Under these circumstances they are to be regarded simply as saprophytes.

Reports of Societies

CLINICAL CONFERENCE, NEUROLOGICAL INSTITUTE, FIRST DIVISION, NEW YORK.

NOVEMBER 12, 1914.

DISSEMINATED SCLEROSIS, MID-BRAIN TUMOR, GENERAL PARESIS. DIFFERENTIAL DIAGNOSIS.

DR. JOSEPH COLLINS presented a case illustrative of the great difficulty which one has at times in distinguishing between disseminated sclerosis, mid-brain tumor and general paresis. The patient, a married woman 35 years old, had nothing in her family or personal history worthy of note, save that when she was 20 she suffered from huskiness of the voice for some days. When she was 30 years old huskiness of the voice developed again and she consulted a laryngologist in Norfolk, Va., who, she says, removed a growth from the throat.

The present illness began suddenly in March, 1913, with (1) a sensation of choking. She was unable to speak for five or ten minutes, after which she recovered completely. A week before she had been shocked by the sudden death of a woman who boarded at her house. She was quite well until January, 1914. (2) Suddenly the arms and legs felt numb, stiff, and a sensation of pins and needles in the extremities, and afterward she experienced awkwardness in using the hands. She made no attempt to walk during the attack. This lasted about five minutes. Off and on until October, 1914, she had similar attacks, always with complete recovery in the interim. (3) In July, 1914, while walking on the street the right leg began to jerk so that she

could not walk. The jerking gradually extended to the right arm, to the right side of face, the entire right side. She became unconscious about ten minutes after the jerking started and remained so for about three minutes. She was told that the jerking persisted during this time, and that she frothed at the mouth, and made a gurgling sound in her throat. No injury or incontinence. (4) After the attack she could not talk for about fifteen minutes. Since then her speech has been hesitating and it has been difficult for her to articulate words although there is no difficulty in thinking, reading, or understanding words. Speech has gradually become worse since July. There has been no remission in the symptoms. (5) Since the attack in July there have been transient attacks of diplopia. (6) Up to October 1st she had several twitchings of the right leg and arm, without loss of consciousness. During the convulsion she could not speak. After the attacks, she would have violent occipital headache, nausea, and at times vomiting. No scotomata or dizziness. Since August at times she has a sensation of tightness in the left side of the head and a "funny" noise like the noise of the elevated cars. The sound is in the head and not the ear. These attacks last one to three minutes and are not associated with any other symptom.

In September her relations noticed that she swerved to the left when she walked. She had noticed that she laughed involuntarily when talking at times. Also felt as though nose pulled to the left and downward.

On October 12th, she caught a heavy cold and had severe occipital headache. On October 15th while writing the right eye-lid began to twitch, soon the twitching also involved the whole right side of the face. Then she felt as though choking and was unable to speak for about a half hour. Had severe headache for two days and vomited several times.

On Oct. 19th she again had a severe headache and was unable to talk for about ten minutes.

On Nov. 7th after returning from a walk, the left leg suddenly began to jerk. The attack lasted five minutes. After this she had another severe headache. Later in the day she was unable to talk for about a minute. During the past year she has lost 15 lbs.

Physical Status.—No evidence of trophic disturbances. The station is slightly unsteady but there is no distinct rombergism. Gait is quite normal. There is a moderate, but distinct, lessened innervation of the right facial muscles of the supra-nuclear type. The tongue is protruded slightly to the right. The palate rises normally on volition. Laryngeal examination negative. No muscular weakness of the arms and legs. There is a slight "intention" tremor of the right hand, which varies in degree from time to time. On two occasions, a slight twitching of the muscles of the right lower face was present when showing the teeth. There is no distinct manual or pedal incoordination. The deep reflexes are all quite active. The right knee jerk is slightly more active than the left. Babinski, Oppenheim, Gordon and Hoffman phenomena are absent. There is no ankle or patellar clonus. The right abdominal and epigastric reflexes are normally active; the left absent. No weakness of the extrinsic muscles of the eyes. There is a slight transient nystagmus on looking upward. The pupils are equal, 3.5 mm. in diameter, rather irregular, and react sluggishly to light, but they react. The fundi are normal.

Examination of the hearing apparatus by Dr. E. B. Dench shows a hyperaesthesia of the auditory nerves to the galvanic tests and failure of the normal overpointing reaction on the left labyrinth is stimulated with cold water.

Sense of position, pain, touch, temperature, reaction time and localization is normal throughout. No stereognosis. The speech is syllabic, staccato in type: both in spontaneous speech and repetition of test phrases.

The Wassermann reaction of the serum and cerebrospinal fluid is negative. The latter shows two cells and an excess of globulin. The urine and blood are negative. Mentally, the patient shows nothing abnormal except moderate excitability and emotionalism which is probably constitutional.

In brief then this patient's conspicuous symptoms are:—

1. Dysarthria.
2. Recurrent headache associated with nausea and at times with vomiting.
3. "Attacks" attended with some perturbation of consciousness, topical paresthesia (side of face, foot, leg) and involuntary movement of the extremities of one side of the body, not always the same side.
4. Transient diplopia.

The physical signs are apparently most trifling:—

1. A very slight difference of innervation of the sides of the face, the right side being slightly sluggish.
2. Unelicitable abdominal reflex on the left side, and
3. Pupils that are sluggish in their response to light.

The speech disturbance is "typically," one may say, that of general paresis. She stumbles over words, elides and slurs syllables, and her articulatory efforts are slow. This disorder of speech is variable in intensity. It is always accentuated after a so-called attack, and when she remains for a considerable time free from attacks it is much less noticeable. Another sign of general paresis is the condition of the pupils. They are slightly irregular and sluggish, though responsive to light, a condition which one who examines many patients with syphilitic nervous disease is apt to call "beginning Argyll-Robertson pupils." Yet despite these two signs we must without reserve rule out general paresis because of the absence of any disturbance of the mental content, and the absence of the Wassermann reaction in the blood serum and cerebrospinal fluid.

On first thought the most probable diagnosis is disseminated sclerosis. The speech disturbance, the transient attacks of diplopia, the absence of the abdominal reflex on one side are all suggestive of this disease. Moreover the patient is of the appropriate age for the occurrence of disseminated sclerosis. But in view of the other striking symptoms which she has, namely the headache, nausea and vomiting, the transient regional paresthesias of "an explosive nature," the periodic twitchings or convulsions of the extremities of one side of the body and the two attacks of loss of consciousness followed by what must be described as a queer mental state, the diagnosis of disseminated sclerosis must be abandoned. This leaves us in the position of being obliged to make the diagnosis of mid-brain tumor. As a matter of fact aside from the absence of choked discs or papilledema the clinical

picture which she presents is fairly typical of mid-brain tumor, if any clinical picture can be said to be "typical" of tumor in this location. It need not astonish us that the optic nerves are not involved in this case, granting that a tumor exists. There are many cases on record of mid-brain tumor in which papilledema did not develop until late in the course of the disease. The occurrence of choked disc depends entirely upon when the tumor produces sufficient increase in intracranial pressure to cause an optic neuritis.

The attacks which she has, must, I think, be interpreted as lower level fits, using the term which Hughlings Jackson introduced to describe a form of convulsion caused by irritation of the motor pathway below the level of the corona radiata. As a matter of fact the onset of her symptoms, the course of the disease, or what may be called the behaviour of the symptoms, and the grouping of the symptoms at the present time, are all more in keeping with the diagnosis of mid-brain tumor than with any other diagnosis. In view of the fact that some tumor growths are influenced by arsenic I propose to give her salvarsan and to show her at some future conference.

DR. T. J. KEYSER presented a case of

HERPES OF THE 5TH NERVE OCCURRING IN A WOMAN OF 54, SUFFERING FROM DIABETES.

The patient came to the dispensary on Nov. 9 complaining of severe paroxysms of pain in the right shoulder and right side of neck, face and head.

The present illness began two months ago with severe toothache. Two weeks later she went to a dentist and had the right lower second molar tooth filled. Immediately after this the pain became very severe, extending over the distribution of the lower branch of the trigeminal nerve. The right side of the face became swollen and tender. Gradually the pain extended to the shoulder, neck and head. It occurred in paroxysms lasting two to three minutes. She describes the pain as of an intense burning character. It begins in the shoulder and extends to the face and the head. It is so severe that she screams with pain, and hypodermics of morphia are required to relieve her.

Three weeks ago a herpes suddenly appeared over the right upper chest, shoulder and right side of neck. The burning pain continued as before. On Nov. 8, the offending tooth was pulled. The doctor who was treating the patient before admission found sugar in the urine.

The patient is rather emaciated and very pale. However the mucous membranes are of a good color; there is a moderate general muscular weakness. There is evidence of recent herpes over the right shoulder, the chest to the level of the second rib, the back to the level of the second thoracic vertebrae, the right side of the neck and posterior aspect of the ear. The face showed no involvement. There seems to be some hypersensitiveness to cold and touch over this area. However, the patient is very apprehensive and often complains before she is touched. There is a marked tenderness of the greater occipital, 1st and 2d thoracic, radial and median nerves and the brachial plexus on the right. There is marked pyorrhea alveolaris, but practically no dental caries. Hearing not defective.

There is no tremor or incoördination. The knee jerks are obtained only on reinforcement, the ankle

jerks are absent. The deep reflexes of the arms are present and equal. Babinski and Hoffman phenomena do not exist. There is no disturbance of sensation and postural sense. The patient complains of pain on pressure over all of the muscles and nerves of the lower extremities. This tenderness varies a great deal on different examinations.

There is evidence of consolidation of the base of the left lower lobe, the percussion note is dull, the breath sounds are high-pitched, bronchial with prolonged expiration and bronchophony. A few moist râles are heard at both bases.

The serum Wassermann is negative. The urine shows $\frac{1}{2}\%$ of sugar, a trace of acetone and albumen. Blood pressure, 160. The blood examination is negative except for a leucocytosis of 86%.

The case is of interest in that the onset of pain over the distribution of the lower branch of the right trigeminal nerve following caries of a tooth suggests an ordinary trifacial neuralgia. However, the further extension of the pain over the distribution of the right cervical and first and second thoracic nerves, the development of herpes, and the tenderness of the nerve trunk and calves, recurring in a patient with diabetes, suggests rather the diagnosis of a mild multiple neuritis of diabetic origin.

PERIODIC RECURRING TIC RESEMBLING EPILEPSY.

DR. J. M. STEPHENSON presented from the Second Division of the Hospital a young woman 18 years old, born in this country of Swedish parentage. Father is 46 years old, living and well; mother 58, living and well. Patient is the seventh of nine children, of whom five died in infancy. Her mother first married at 25 years; first child died at one week; second child, born one year later, now 31 years old, apparently normal; third child born two years later, died at three years, convulsions; fourth child, girl, living and well, now 27 years old; fifth child died at three years, convulsions "teething"; the father of these children died of grinders' consumption. The mother married again at the age of 37, her husband being 25 years old at the time. First child of this marriage, a girl, living and well, now 21 years old; seventh child, the patient; eighth child still-born $2\frac{1}{2}$ years later; ninth child died at two years (?), was never well.

Gestation apparently normal; labor relatively normal; low forceps, 10 pounds. Breast fed one year; talked and walked at one year; strong and healthy during infancy. Whooping cough and measles at $1\frac{1}{2}$ years without apparent sequelae; spinal meningitis (?) 1903 (at the time of an extensive epidemic of actual spinal meningitis in this vicinity) starting with bunches in the neck, followed by pain in the head and back; in bed for many weeks and very sick. Since then she has never been as strong and well as previously. Some time later she had influenza with inflammation in one ear, which broke and ran for some time and left her a little deaf. Later she had neuralgia about the heart with sinking spells, which usually consist in the occurrence of black and red bunches on the heels, then on the palms of the hands, and then it would go to her head. She would scream and then faint for two or three minutes and lie so still that they could not hear any breathing or beating of the heart. This occurred about twice a day for two weeks, and she was under the care of a physician, who called the condition nervous

prostration. He made her get up and walk around, and after that she was all right. Three years ago, at the age of $15\frac{1}{2}$ years, she had inflammatory rheumatism with swelling and pain in her legs, hands and neck, and was very sick for one week. One year ago she had bronchitis. Tonsils were removed six years ago, before which time she had tonsillitis frequently. She has noted some shortness of breath in rapid walking. One physician said she had anemia; another physician said she did not have any anemia. In January, 1914, she weighed about 140 pounds, but had lost quite a little weight during the previous few months. Menses began at 12 years, were regular, and did not cause much discomfort. She started to go to school at five and was in the eighth grade at the age of 14, when she had to stop on account of the present illness. Since then she has been at home in a small village with her father and mother, and helps about the house.

Since August, 1910, she has had "spells," occurring at intervals ranging from three or four days to one or two months, with a single long interval of 10 months three years ago. I saw her first in January, 1914, and since then these attacks have occurred on the following dates: Jan. 14 and 30 at 9 a.m.; Feb. 26, 10.30 a.m.; March 18, 4.05 p.m.; April 17, 2.35 p.m.; May 18, 3.45 p.m.; June 16, 12.40 p.m.; July 12, August 17, Sept. 16, Oct. 17. During July and August the menses occurred at intervals of two weeks.

The patient describes her condition as follows: "I have these spells: a funny feeling comes in my stomach and chest, and then it twitches me all over. The left side is the worse. They last more than half an hour. I am awfully weak after it and twitchy for several days. My hands and legs shake. I do not lose consciousness and I know what is going on and can talk. I fall down because I can't walk, because my left ankle goes right under me. I usually bite my tongue."

The sister states that the patient usually introduces the attack by saying, "It is coming, mother," and then falls down if she is not caught. Her fingers twitch and close up; she turns her eyes up and her feet in. The next night she shakes the whole bed, but may sleep for a minute of the time, and then wake up with a jump. Afterwards she is very tired for several days.

Patient entered hospital Nov. 7, 1914. Examination revealed a well nourished young woman; musculature well developed; no atrophies; station good; gait good; no ataxia or tremors at rest or on intention.

Pupils round, regular and respond well to L. and A. Mobility O. K. No contracture of fields nor corneal reduced sensibility. Eye report by Dr. Holden, slight astigmatism.

All reflexes were present, fairly active and equal. Plantar responses flexor. Abdominal and epigastric present and equal. Sensations intact. Wassermann negative. Blood showed 83% hemoglobin. Urine negative. Blood pressure ranged between 110 and 122.

On Nov. 10 had an attack described by Dr. McRoberts, the house physician, as follows: "She lay on the bed with legs drawn up, partly on back and partly on right side. Left arm and leg jerking in irregular violent clonic spasms. Occasionally the left side of mouth would twitch and the right arm and leg shook slightly; mostly from the general mo-

tion the body was thrown into by the left-sided spasms.

"She complained of pain in her neck and hip, and asked that something be done for her. She was perfectly conscious throughout the attack, which persisted violently for nearly forty minutes, and in a measure for several hours later.

"She responded to all questions and opened her mouth for examination of throat. Sensation remained equal in both sides of body according to patient's statements. No corneal or pharyngeal anesthesiae. No loss of stereognostic sense in convulsed hand. Pupils responded to light and the accentuated knee jerks were equal. Left ankle jerk more difficult to obtain on account of resistance of muscles, but when obtained was equal in response to right. Plantar response flexor. No clonus.

"No opinion of abdominal reflex can be given on account of continual spasm. No incontinence. Tongue could be protruded and maintained out for examination easily. No headache, no confusion, no increase in severity after commencement of spasm.

"The spasm involved mostly the pectoral and shoulder muscles. The fingers would open and close irregularly and easily flexible with exception of little finger, which was maintained throughout (almost) in tonic contraction."

Patient continued to have the spasms until about ten that evening, when they are said to have disappeared. However, the next morning they were present, and the first impression made was that of hemichoreiform movements. But upon examination the movements were seen to be not the aimless movements of the chorea, but rather the overaction of volitional impulses. The muscles mostly involved were those of the left shoulder, the movements causing adduction and elevation of the arm. At the same time there was irregular flexion and extension of the fingers, with an occasional contraction of the abdominal muscle and diaphragm. The movements at times were slow, again sudden, causing a quick jerking of the arm inward and upward. Attempts to control the movements aggravated them but distraction of attention somewhat lessened them. The spasms have continued, but are gradually lessening in severity. However, upon close observation, you can observe them now.

The question of diagnosis is an interesting one. Three possible diagnoses present themselves, viz.: Jacksonian epilepsy, including also the so-called basal ganglion explosions; hysteria; and tic. It is hard to conceive that one could have seizures so frequently over a period of many years of a cortical or basal origin without showing some organic manifestation, such as increased reflexes, etc. These being absent, I think we can eliminate an organic etiological factor.

The diagnosis of hysteria is always a dangerous one and in my opinion should never be made unless there is at least one of the stigmata of hysteria, not one of which is present in the patient.

By a process of elimination, I arrive at the diagnosis under which I desire to present this case, viz., periodic recurring tic. Here we have a patient of neuropathic constitution, indicated by her previous history, upon which field such maladies develop. We have a young girl who for the past year has had regular monthly "spells," so regular that the family can almost predicate the date. The spells are always of a similar nature, consisting of irregular contractions, involving mostly the shoulder girdle, movements being more those of overaction of nor-

mal impulses, aggravated by attempts to control, lessened by distraction, showing none of the findings produced by organic disease of the central nervous system, and none of the stigmata of hysteria.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

MEETING OF WEDNESDAY, NOVEMBER 4, 1914, AT 8 P.M.

The President, DR. JAMES C. WILSON, in the chair.

PAIN AND TENDERNESS IN DISEASES OF THE SPINAL CORD AND THEIR SURGICAL TREATMENT.

DR. CHARLES A. ELSBERG, New York: The tremendous development of abdominal surgery has brought with it a great advance in our diagnostic acumen. Strange to say, however, little attention has been given to the neural origin of abdominal pain. The abdominal symptoms of locomotor ataxia are well known, yet in not a few cases operations have been performed for supposed gastric disease when the real trouble was gastric crises in the course of tabes. During the past five years two patients have been sent into my service in one of the hospitals in New York with the diagnosis of acute appendicitis. In both instances the patients had Pott's disease with irritation of spinal nerve roots, and areas of skin and muscle tenderness in the right iliac region. I have records of three patients in whom various operations had been performed who were finally found to have a spinal tumor or a neuritis of the nerves of the cauda equina. Another patient operated upon for supposed gangrene of the toes with severe pain shooting down the leg was finally relieved by an operation for spina bifida occulta. To understand the distribution of painful symptoms in the extremities it is of value to remember the anatomy of the spinal nerve roots. There is a marked difference between the cervical and upper dorsal, and the lower dorsal and lumbosacral posterior roots. In the latter the nerve fibres which originate from the cord soon unite to form one bundle,—the posterior nerve root; in the former, however, the bundles of fibres which originate from the cord along a line from one to one and one-half centimeters in length do not unite to form the posterior root until near to where they perforate the dura. As a result a tumor may press upon some of the nerve bundles without compressing the entire spinal root. This anatomical arrangement enabled us to understand the early symptoms of a patient from whom I removed an extramedullary tumor of the spinal cord between the seventh and eighth cervical segments, whose first and for a long time only symptom was a painful pin and needle sensation in the index finger of the right hand. At operation the tumor was found to have pressed upon only the lower nerve root bundles of the seventh cervical posterior root. From several cases of this kind I feel justified in making the statement that of the nerve bundles that make up the seventh cervical posterior root, the lower supply the index finger and the upper the thumb,—an interesting fact for finer spinal localization. There are many abdominal disturbances that patients suffer from which are but little understood. In my last 100

laminectomies for spinal disease I have performed six operations on patients who had been treated for long periods for abdominal symptoms. In every case of indefinite abdominal pain and tenderness it is advisable to make certain that we are not dealing with a cutaneous hypersensitiveness, which so often simulates real abdominal tenderness. Before doing a root section for gastric crises I believe there should always be given a preliminary intraspinal injection of stovain. By this means will be gained a fair idea of the prospect of success from division of posterior roots. The operation of Spiller and Martin for severe pain of peripheral or of spinal origin is based upon a sound anatomical and physiological foundation and the future for the operation is a very bright one. The question of whether the spinal cord is sensitive to pain, or like the brain, insensitive, is a subject to which I have been giving some of my time and attention. I have observed patients upon whom lumbar puncture was done, others upon whom spinal operation was done under local anesthesia. Finally, I have attempted to learn something on this subject in the course of some experiments upon animals. Other attractive subjects for study are the pathological mechanics of spinal compression, and a more intensive study and comparison of the sensory and motor disturbances which occur on each side of the body when the spinal cord is pressed upon by a new growth or as a result of an inflammatory or traumatic lesion.

DR. CHARLES W. BURR: In a patient seen some years ago the only symptom present was diffuse pain in the right arm. Later there was slight wasting in the muscles around the thumb. The pain was later replaced by painful anesthesia accompanied by marked wasting and gradually increasing palsy in the whole arm. After some time death ensued and at post mortem there was found in the cervical region a long flat growth that had entered the nerve roots, first the posterior, causing only pain and then the anterior, causing pain and wasting. Had we but known the cause of the trouble, operation would have saved her a great amount of pain and probably her life. The more we learn of the distribution of pain in reference to the nerve roots affected, the more we shall be able to do in all of these cases.

DR. CHARLES H. FRAZIER: My experience in operating for the relief of pain consequent upon spinal lesions has been confined to cases of tumors operable and inoperable of tabetic crises, and of persistent neuralgia following injuries to the brachial plexus. I think it is too commonly supposed that pain is a constant and conspicuous symptom of spinal tumor referred to the peripheral distribution of the segment involved. A number of cases of spinal tumors have been observed in which throughout the course of the lesion there was absolutely no pain. The widely varying results of rhizotomy would seem to throw some doubt upon the present conception of the pathways of afferent impulses and to suggest the possibility of the ventral roots having some part in the carrying of afferent impulses. Such hypothesis has been already advanced by Kidd. Whenever possible, a therapeutic test should be applied before operation in order to determine whether interruption of the sensory impulses does not relieve pain. Spiller's suggestion of resection of the anterolateral column of the cord is a most valuable one and appeals to me particularly in cases of uncontrollable pain of the lower extremities and more especially because the operation does not necessitate

the removal of as many laminae of the spine as would be necessary to cut the required number of lumbar and sacral roots. In the limited number of root resections for pain in my own clinic there have been no fatalities, but in a larger series, performed by a number of surgeons, the mortality rate has been estimated at 10%. This I believe is too high and that the risks of the operation should be materially reduced. The low rate of mortality in my own experience with laminectomy I attribute chiefly to intratracheal anesthesia and to the use of the stovain block.

DR. ELSBERG: I am not very enthusiastic about cutting posterior spinal roots in the treatment of the crises of tabes. Professor Forster states that the only way to get a fairly good result is by an enormous laminectomy, cutting from the fourth or fifth dorsal down to the twelfth, and that even then the result is not certain. I have seen temporary benefit from the injection of stovain into the spinal canal. Laminectomy is an operation in which the mortality should be very small and one which a surgeon after a little experience should be able to do easily. In 98 successive cases we have had no mortality.

THE PATHOLOGY OF TABETIC OCULAR PALSIES.

DR. WILLIAM G. SPILLER: The causal relation of syphilis to tabes and paresis is now fully accepted and gradually the view has gained headway that tabes and paresis are really syphilitic and not parasymphilitic diseases. This opinion has been greatly advanced by the discovery of Noguchi and Moore of the spirocheta pallida in tabes and paresis. The present status of the syphilis tabes paresis question has been fully discussed by Nonne. It has taken many years to establish what is now known in regard to this matter, and it has become evident that some of the sharp distinctions between tabes and paresis, on the one hand, and cerebrospinal syphilis on the other, need modification. This does not mean that we must drop the designations of tabes, paresis and cerebrospinal syphilis. The ocular palsies of tabes have been regarded by some investigators as nuclear in origin and the syphilitic ocular palsies as of nerve origin. This view may be disputed. I have studied by microscopical serial sections a typical case of tabes with complete internal and external ophthalmoplegia. The ocular nerves and their nuclei were much degenerated, there was considerable round cell infiltration of the pia, but one of the abducent nerves which was less degenerated than the other showed also less round cell infiltration within the nerve. Round cell infiltration is indicative of the intensity of the syphilitic process. This case would throw doubt on the view that tabetic ocular palsies are nuclear.

DISCUSSION.

DR. CHARLES K. MILLS: Dr. Spiller's paper is another contribution to our exact knowledge of the well known phenomena of tabes and another contribution to assist us in bringing together so-called parasymphilitis and syphilis, or rather to break down the artificial partition which has been reared for so many years between these so-called different specific diseases. We can understand some of the well known early phenomena of tabes better by recognizing the position which Dr. Spiller takes regarding these ocular palsies. As an example, it is not

at all uncommon for the diplopia often present in early tabes to rather quickly disappear. I take it that this would not occur were the palsies due to nuclear degeneration.

DR. DANIEL J. MCCARTHY: Certainly syphilis of the brain and of the spinal cord reacts entirely different to treatment with mercury or salvarsan from tabes and paresis. The accumulation of statistics from salvarsan and other treatment leaves little doubt that, while there is a certain amount of symptomatic improvement, there is little evidence of clear cut cures in tabes, and none in well-developed paresis. There is a group of diseases of syphilitic origin which reacts fairly well to treatment. I would ask Dr. Spiller whether in his opinion tabes still exists, or whether all cases of tabes should be grouped together as spinal syphilis. My feeling is that we have distinct cerebral syphilis which reacts to treatment. Apart from this, paresis on the one hand and tabes do not react, and when once developed are practically incurable.

DR. SPILLER, closing: We recognize tabes and paresis, but we must regard them as truly syphilitic diseases. Tabes is caused by the degeneration of the posterior roots from the syphilitic poison. There are cases in which a positive diagnosis between spinal syphilis and tabes cannot be made. There are also cases in which the diagnosis between cerebral syphilis and paresis cannot be made, and these cases show how close the connection between cerebrospinal syphilis and the so-called parasymphilitic diseases may be. From my study of the effects of syphilis on the nervous system and from a reading of the literature I have formed the opinion expressed in my paper.

NEW ENGLAND PEDIATRIC SOCIETY.

MEETING OF DECEMBER 4, 1914, HELD AT THE BOSTON MEDICAL LIBRARY.

The President, DR. C. A. PRATT, of Fall River, in the chair.

The following officers were elected for the ensuing year:

President, DR. E. M. BUCKINGHAM, Boston, Mass.

Vice-President, DR. E. F. CURRY, Fall River, Mass.

Secretary and Treasurer, DR. RICHARD M. SMITH, Boston, Mass.

Member of council for three years, DR. FRITZ B. TALBOT, Boston, Mass.

The following papers were read:

CHILDREN WITH POSITIVE SKIN TUBERCULIN REACTION.*

By ORVILLE F. ROGERS, JR., M. D., Boston.

TRAUMATIC RUPTURE OF INTESTINE.†

By LINCOLN DAVIS, M. D., Boston.

A CASE OF ACETONURIA.‡

THE SIGNIFICANCE OF THE X-RAY GASTRO-INTESTINAL FINDINGS IN CASE OF CONGENITAL STENOSIS OF THE PYLORUS, FOLLOWING POSTERIOR GASTROENTEROSTOMY.§

By CHARLES L. SCUDDER, M.D., Boston.

SOME STUDIES IN FAT INDIGESTION.¶

By CHARLES HUNTER DUNN, M.D., Boston.

DISCUSSION.

DR. C. W. TOWNSEND, Dr. Davis's paper: I would like to ask Dr. Davis what percentage of mineral matter there is in ordinary tap water. I supposed that pure water was an irritant to the mucous membrane, and the fact that tap water works as well as salt solution would rather indicate that there was some mineral matter in it.

DR. F. B. TALBOT, Dr. Parker's paper: This type of case is extremely interesting, because we know so little about the real cause of vomiting associated with acetonuria. Curiously enough, a number of cases that I have seen with acetonuria and vomiting have all had acetone in the urine as soon as I was able to get a specimen. That does not mean that the acetone preceded the vomiting in all these cases, but there are many cases such as one I have at present in the ward at the Massachusetts General Hospital which has a large amount of acetone in the urine and who has not yet vomited. Associated with the acetonuria and vomiting there is evidence of an intolerance to fat, and my clinical experience has been that the majority of these cases have done better and have had fewer attacks when the fat has been entirely cut out of the diet.

DR. C. A. PRATT: I have seen two out of six children with this condition die, which is rather a large death-rate, I think.

DR. W. S. PARKER in closing: I had a report very recently on this case which was operated on. General microptosis and a much dilated cecum were found. The cecum was unfolded and the transverse colon suspended. No attacks were recorded for ten months, when they recurred with very moderate severity and nothing like the former frequency; they have diminished from that time on, and the last letter from the parents states that they regard the operation as a complete success as far as cure is concerned. This is rather unusual, as the constipation is still very extreme.

DR. F. B. TALBOT, Dr. Scudder's paper: I agree in general with everything Dr. Scudder has said, but I would like to know how he answers the question which is raised that in the majority of these babies they do not begin to vomit until they are about ten days old. I would like to know how he explains that fact and why, if there is a congenital tumor at birth, we do not have vomiting from birth?

DR. C. G. MIXTER: Last year, I reported before this Society, five cases which we had had in our clinic at the Children's Hospital, which were followed through their ultimate course after operation with x-rays, and which substantiate Dr. Scudder's pictures entirely. Furthermore, we had one case in which, several months after gastroenterostomy, a stomach-tube was passed—it went into the duodenum, then came to a halt, was deflected upward and around, and finally went out through the

§ See JOURNAL, page 166.

¶ See JOURNAL, page 167.

stoma, after making a complete circle, showing that the pylorus was still sufficiently obstructed to resist the pressure of a stomach-tube above it. I have seen other cases also since that time, the time of course being short, but in all the obstruction has remained.

DR. SCUDDER: There is no longer any doubt that the tumor in these cases is congenital. There has been a case reported—one that we all have been on the lookout for—a still-born baby, a fetus, in which the congenital tumor was present. It is the first instance reported, and it establishes the fact that the tumor is congenital.

In answer to Dr. Talbot's direct question, "Why do not these babies vomit from birth?"—the average time of vomiting is from two to three weeks in a large series of cases. Some of them do vomit at the end of the first week. Some spit up a little just after birth. One reason that has been attributed for their beginning to vomit at the end of a week is that the mother's milk begins to be secreted copiously at this time. The ingestion of this larger quantity results in spitting up and vomiting. I believe that the tumor exists at birth and that the lumen of the pylorus is obstructed to a variable extent, the obstruction differing in each case. In some cases it is nearly complete, in others it is much less. Therefore, remembering that each individual needs a certain lumen to his pylorus to get food through without vomiting, it is fair to conclude that if the pylorus is sufficiently patent, there will be no vomiting; if it is not sufficiently patent, then vomiting begins.

Instead of supposing that a pyloric spasm exists in these tumor cases, it seems to me that it is more reasonable to suppose that the edema of the mucous membrane and the swelling of the pyloric ring are competent to occasion a rather sudden narrowing, and the onset, therefore, of vomiting. It is true that all parts of the child grow rapidly during these first few weeks, and this tumor will grow, thus obstructing more and more. The answer to the question why vomiting occurs at different periods is that there is a mechanical and not a physiological cause at work. I think it unnecessary to introduce the physiological functional element seen in the contracting pyloric sphincter. The purely physical explanation is entirely adequate. The edema of the mucous membrane, the increased swelling of the longitudinal fold that normally exists within the pylorus, and the natural growth of the tumor itself, all adequately contribute to the obstruction.

DR. K. G. PERCY, Dr. Dunn's paper: I would like to ask Dr. Dunn if in this series he has seen two types:—one of straight fat indigestion, and the other of fat indigestion plus a carbohydrate indigestion. Are these latter not primarily carbohydrate indigestion? You say, that in your series, these cases with sugar indigestion as a complication have not shown a gain on any special type of milk formula even lactic acid milk. We have been following the cases of diarrhea at the Children's Hospital with the gas bacillus test and Dr. Sylvester has been following the fat indigestion cases with the same test. Many of these cases, having secondary inability to take care of sugar, were positive for gas bacillus and did well on butter-milk, both in regard to weight gaining and later, acquiring their ability to take care of fat. Have you found this same phenomena, which we believe typical of a special type of, so-called, fat indigestion?

DR. H. A. GALE: Was maltose tried in the beginning of treatment of these cases and did it prevent blow-ups?

DR. H. A. GALE, Dr. Dunn's paper: I would like to ask Dr. Dunn a question, and that is whether or not there is any record of the proportion of those cases in which cane sugar seems to do the damage. My impression is that most of the cases of straight fat indigestion have been either on starch mixtures or cane sugar mixtures. I would also like to ask if there was any attempt made to replace the bovine fat by the other fats. That has been done in some places, although no definite results have been reported as yet.

DR. F. B. TALBOT, Dr. Dunn's paper: I notice that Dr. Dunn said that in one of his cases he had found tuberculosis. In infancy the tubercle bacillus usually gains entrance through the glands and in a large number of instances through the mesenteric glands. In a series of cases¹ which I studied two or three years ago I showed that when all the mesenteric glands were tubercular and functionally destroyed, that fat would be digested but not absorbed and as a result fat was found in the stools. Such cases, of course, are not cases of fat indigestion *per se*, they are cases of tuberculosis. Furthermore, it is conceivable that a similar condition can be present in hereditary syphilis, although it has not been proven. Such cases are very difficult to feed and their stools are likely to contain fat; they are sometimes classified as cases of fat indigestion, but they get well if put on proper antisyphilitic treatment. In regard to soap stools, I have found it very difficult to tell whether there is more soap or less soap in a stool. It is very easy to say whether there is soap or not, but when a stool becomes a soap stool, my experience has been that practically all the stool is soap and there is no "more" or "less." To my mind the most important factor in these very difficult cases of infant feeding is the balance of the food, that is the relation of the fat to the carbohydrate, and the protein, and of the sugar to the fat, and so on. In a great many cases in which the stools have been loose and have contained free fat, in other words, fatty acids, I have been able to change the stool into a soap stool very easily, merely by changing the balance of the food, that is, a food with a high percentage of protein and a relatively low percentage of fat and sugar. Last year Dr. Hill and I² reported the metabolism of a baby in which the sugar in the food was increased about 3% at a time. We measured the fat, the nitrogen, and the carbohydrate metabolism, as well as the sugar. When the food got beyond the limits of tolerance for sugar the baby had symptoms of indigestion which were due to the sugar. The stools contained a great deal of fat, which they did not contain before. That was not a case of fat indigestion, but a case of sugar indigestion. The digestion of sugar and the fat is so intimately connected, that it is almost impossible to say what element was the primary cause of the indigestion, the fat or the sugar, without previous knowledge of the course of the disease, and I wonder how Dr. Dunn was able to tell that these cases were all cases of fat indigestion. A word as to my feeling as to the action of protein. I look upon buttermilk, Eiweissmilch and precipitated casein as foods in which the

¹ Tuberculosis of the Mesenteric Glands in Infants and Young Children: Its Effect on Absorption. Am. Jour. Diseases of Children, 1912, iv, 49.

² The Influence of Lactose on the Metabolism of an Infant, Am. Jour. Diseases of Children, 1914, viii, 218.

action comes more from the form of protein than because it is Eisweissmilch, buttermilk or what not. In other words, it is a protein that cannot be coagulated again. My experience has been that boiling the milk gives practically the same results as buttermilk, precipitated casein or albumen milk. I was very much interested in Dr. Dunn's paper, and I hope there will be more papers like it.

DR. C. L. SCUDDER, Dr. Dunn's paper: How many cases were observed during this period in this study?

DR. C. H. DUNN, in closing: Thirty-five cases comprise the statistical table which I am at work on.

In answer to Dr. Percy, I will say that we did see carbohydrate, or signs of carbohydrate indigestion in the course of some of these cases, but whenever it occurred we could relieve it very easily, but the fat indigestion we could not relieve so easily. Also there is a large series of cases that came into the hospital which were diagnosed as carbohydrate indigestion only. They gave the symptoms of acid irritating stools, gas, green movements and vomiting, but they were very easily relieved and soon discharged. In those cases when we gave moderate amounts of carbohydrates we did not see signs of carbohydrate indigestion after they entered the hospital. The only time we saw it was when we attempted to experiment by increasing the amount of carbohydrates.

DR. GALE'S question: A certain number of cases were on maltose preceding a "blow-up," with an increasing amount of fat in their stools; fully as many cases in the series showed fat "blow-ups" on maltose as on lactose. Possibly we had more on maltose. The maltose seemed not so much of use in preventing the "blow-ups," but it allowed us to obtain a gain in weight with a small amount of fat. It nourished the baby better, but did not increase the fat tolerance.

DR. PORTER'S question: I am by no means convinced myself from our evidence that the cow's milk salts do not play an important rôle in these cases. In fact, we entered the investigation rather in the hope of obtaining evidence to that effect. The method of using precipitated casein and alternating with whole milk protein is a rather crude one, anyway. What we would like to do if we had enough breast-milk would be to repeat the experiment of using human milk fat with cows' milk, whey and vice versa. It seems to me it would give very definite evidence as to the rôle of the salts. All we were able to conclude was that we did not get the advantage from feeding the precipitated casein and diminishing the salts that we expected to get when we began the investigation. There were certainly cases in the series which did better on precipitated casein, but there were others which did not.

Dr. Talbot has spoken about estimating the amount of fat as soaps in the stools. I do not believe that our method is an accurate one at all, but we are endeavoring to adopt a standardized method which we will transmit from house officer to house officer. The method is simply to take a definitely measured portion of the stool and mix it with Sudan III and acetic acid, boiling, and then estimating the results by the concentration of the globules. This is a very crude method, and although we have what we call a sliding scale, yet the evidence of the actual amount of fat as shown in this way does

not amount to very much—it is either a soap stool or it is not.

The importance of maintaining a balance between the fat, carbohydrates and protein I quite agree with. You have got to keep the balance more or less constant or some form of indigestion will surely follow. Dr. Talbot asked whether they were all cases of fat indigestion or whether some of them might not have been carbohydrate indigestion. I might say that we did not classify them as to what was the possible primary condition. We classified as carbohydrate indigestion those which did not show fat indigestion, cases showing symptoms of carbohydrate indigestion which were relieved when the carbohydrates were cut down or changed. The other cases which showed fat in the stools we classified as fat indigestion without reserve. The only evidence which I have on that point was obtained from looking over all the histories, which we went into as carefully as possible. This frequently suggested carbohydrate overfeeding, and it was on that basis that I suggested that the carbohydrate fermentation seemed to be a very possible primary cause, and I think that the relationship between fat and carbohydrate indigestion is very close, just as Dr. Talbot has stated.

Book Reviews.

Therapeutics of Dry Hot Air. By CLARENCE EDWARD SKINNER, M.D., LL.D. Third edition. Thoroughly revised to date. Hammond, Indiana: Frank S. Betz Company. 1914.

The first edition of this book was reviewed in the issue of the JOURNAL for Jan. 29, 1903 (Vol. cxlviii, p. 128). The second edition, published in 1905, contained a number of additional case reports, several new illustrations, and a number of technical details. This third edition has been largely rewritten so as to embody and conform with recent advances in knowledge, and contains a new chapter on the incandescent electric light as a local therapeutic agent. It is illustrated with 40 text-cuts. It has the merits and defects of its original, and, in the words of our previous review, "cannot be called a judicial statement of the uses and limitations of this mode of treatment."

Modern Medicine. Its Theory and Practice. In Original Contributions by American and Foreign Authors. Edited by SIR WILLIAM OSLER, Bart., M.D., F.R.S., and THOMAS MCCRAE, M.D. Volume III. Diseases of the Digestive System—Diseases of the Urinary System. Philadelphia and New York: Lea and Febiger. 1914.

The third volume of this standard work now appears in its second edition. This volume takes

up diseases of the digestive system and of the urinary system. The plan of the first edition has been followed. There are authoritative chapters on the various aspects of the diseases of the two systems covered in this volume. These chapters are written by men who have done notable work in the fields that they discuss. It is sufficient to say that this volume, like its predecessors, leaves very little to be desired in the complete and up-to-date discussion of the subjects to which it is devoted.

Diseases of the Rectum and Anus. A Practical Handbook. By P. LOCKHART-MUMMERY, F.R.C.S., Eng., Senior Surgeon to St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum; and Surgeon to the Queen's Hospital for Children; Late Hon. Surgeon, King Edward VII Hospital for Officers. New York: William Wood and Company. 1914.

This small volume of 350 pages is written by an Englishman and published in New York. Mummery says: "The material for the book has been gathered from my own experience in private practice and at St. Mark's Hospital. This hospital affords unrivalled opportunities for studying diseases of the rectum, for only diseases of the bowel are treated there, and the attendances in the out-patient department are over 7500 in the course of a year, while cases admitted to the wards average about 650. It is much to be regretted that while numbers of doctors from America, the Colonies, and abroad generally, attend the practice of this hospital, the number of English doctors who avail themselves of the clinical material to be found there is deplorably small." The author goes on to state that nearly 50% of the population, presumably of England, have some rectal trouble sometime in their life. He tells us that the book is a practical guide to the treatment of rectal diseases, and that most of the drawings are his own.

The book is much smaller and more compact than either of the volumes on the same subject recently reviewed in this JOURNAL. It has that curious omission of a chapter on Anatomy, which certainly detracts from the value of the book. The treatment of the various conditions described, (and everything which probably comes within the domain of proctology, is described), is brief, definite, and positive. Simple procedures are invariably given preference. The author emphasizes repeatedly the importance of post-operative treatment, and since he is in charge of a special hospital, to which only rectal cases are admitted, he has excellent opportunity of judging both the satisfactory effects of efficient post-operative treatment and the unfortunate results which follow too frequently the average treatment in the hands of the average practitioner.

We notice with surprise that he does not recommend dilatation of the sphincter before operation for internal hemorrhoids. The author's own operation of perineal excision of the rectum is described in much detail, although he frankly says, "It is now, to a large extent, replaced by abdominal-perineal excision." He has had some excellent results by this method; several cases which have already passed the five-year limit. He comments on the similarity between his operation and that of Quénu, and of Hartmann, of Paris; but his own operation was worked out without knowledge of either of the others. In colostomy, he recommends the opening through fibers of the rectus muscle.

There is no bibliography, and comparatively few references to other authors, none to American authors, with the exception of Tuttle. On the whole, however, the book is an excellent small text-book. Its printing, paper, and illustrations are very satisfactory.

The Backward Baby. A Treatise on Idiocy and the Allied Mental Deficiencies in Infancy and Early Childhood. By HERMAN B. SIEFFIELD, M.D., New York. Awarded the Alvarenga Prize of the College of Physicians of Philadelphia, July 14, 1914. pp. 184, with 22 original illustrations in the text. New York: Rebman Company. 1914.

The author states in his preface that "the aim of this prize essay is to present to the profession a practical survey of the etiology, pathology, diagnosis and treatment of the diverse mental deficiencies as they occur in children under five years of age. The existing excellent monographs and text-books on the subject are," as he truly states, "almost exclusively devoted to the study of feeble-mindedness in children of school age and adults." There was, therefore, an opportunity to write an epoch-making book. Unfortunately, the author has not taken advantage of this opportunity, but has instead written a superficial and incomplete treatise on the subject. It is interesting and instructive, but falls far short of what it might have been. We hope that he will take advantage of the opportunity and, using this book as a basis, write a new one.

A Mind Remedy. By JOHN G. RYERSON, M.D. Boonton, N. J. 1914.

The writer's idea as stated by himself is that he proposes to show that scores of the most common diseases have such a uniformity of symptoms as to be justly classed as one disease, and that he has found what is practically a specific for this disease, which is lactose. The large number of cases, which include asthma, eczema, locomotor ataxia, organic heart disease, interstitial nephritis, difficult labor, puerperal convulsions, and many others, are so imperfectly re-

ported that no conclusions can be drawn; and the looseness of thought which allows the writer to include among his cases some where he claims the figure, or voice, was improved, the apparent age lessened, the hands and feet made smaller by his treatment, does not inspire confidence. This book may be neglected except as a curiosity of medical literature.

A Treatise on Diseases of the Rectum and Anus.

Edited by A. B. COOKE, A.M., M.D., Formerly Lecturer on Diseases of the Rectum and Professor of Anatomy in the Medical Department, Nashville, etc. Assisted by WILLIAM M. BEACH, A.M., M.D., Pittsburgh, Penn.; GEORGE B. EVANS, A.M., M.D., Dayton, Ohio; J. COLES BRICK, M.D., Philadelphia, Penn.; ALOIS B. GRAHAM, A.M., M.D., Indianapolis, Ind.; GRANVILLE S. HANES, M.D., Louisville, Ky.; LOUIS J. KROUSE, M.D., Cincinnati, Ohio; COLLIER F. MARTIN, M.D., Philadelphia, Penn.; FRANK C. YEOMANS, A.B., M.D., New York City; A. J. ZOBEL, M.D., San Francisco, Cal. With 215 illustrations in the text and 21 full-page plates, 7 in colors. Philadelphia: F. A. Davis Company. London: Stanley Phil lips. 1914.

This admirable and rather small volume of six hundred pages treats its subject in an unusual manner. In his foreword, the author says that at least 20 years ago he decided to write a practical treatise on Diseases of the Rectum, based on his own personal experience. "But as circumstances directed my interest and practice into the broader field of general surgery, enthusiasm waned and the work was laid aside when only partially completed." Recently he has revised the previously written chapters and has edited the remainder. The book is, therefore, Dr. Cooke's own text-book in its first half and a series of monographs from the pens of nine specialists in the latter half. Moreover, the rectal surgeon of twenty years ago has now become a general surgeon, and as a result we find a wide general experience concentrated upon a specialty. This is a very desirable and unusual occurrence. The book commences with a very satisfactory chapter on anatomy and physiology. Dr. Cooke's own contributions include most of the commoner conditions of the anus and rectum. The other 14 monographs treat of stricture, benign and malignant tumors, neuroses, trauma, local anesthesia, major operations, and interesting chapters on recto-colonic alimenta-

tion and relation of rectal diseases to the general health. An excellent feature of much of the work is a brief outline at the beginning of each chapter and history of the subject which is about to be considered. The illustrations are numerous and unusually good; in spite of this it has been found possible to eliminate the extreme gloss of the paper so often used for the purpose of illustrations, for which the editor deserves our thanks. The binding, printing, index, etc., are entirely satisfactory. The book is to be cordially recommended; it is really a very admirable hand-book,—long enough, but without a single unnecessary page.

The Tonsils,—Faucial, Lingual, and Pharyngeal.

With Some Account of the Posterior and Lateral Pharyngeal Nodules. By HARRY A. BARNES, M.D., Instructor in Laryngology, Harvard Medical School; Surgeon in the department for diseases of the nose and throat; Boston Dispensary; Assistant Laryngologist, Massachusetts General Hospital; Member of the New England Laryngological and Otological Society; Members of the American Laryngological, Rhinological and Otological Society. Illustrated. St. Louis: C. V. Mosby Company. 1914.

This is a book of 160 pages on the tonsils and the other parts of the tonsillar ring, including their development, anatomy, physiology, pathology and surgery. The author states in the preface that his object is "to put into concise form the facts concerning the lymphoid tissues of the throat," and he has succeeded admirably in doing so. He has combined into a consecutive and attractive manual the results of his work in the pathological laboratory, his experience in a large clinical service and the review of several of the more important publications. The book presents the subject better and more thoroughly than do the corresponding chapters in any of our text-books. It is not encumbered with varying points of view, although the student who wishes to go deeper will find numerous references to other authors. Much has been written in recent years about the tonsils, but this is so scattered that it is not easily available. In collecting this material the author has been guided by his own judgment, which represents the opinion and practice of American authorities of the present day. The illustrations are original and to the point. A better understanding of the tonsillar ring is desirable not only for the laryngologist, but also for the general practitioner and pediatricist, and to all of these this book should be welcome.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, FEBRUARY 4, 1915.

FEDERAL OR LOCAL ADMINISTRATION OF MARITIME QUARANTINE.

In several recent issues of the JOURNAL we have commented editorially on the question of the transfer of the Boston Quarantine Station from municipal to federal control. On January 1, a hearing on this subject was held before the City Council, and at the request of that body a committee of six was appointed by the Boston Chamber of Commerce to study the problem and report at a future meeting.

The special committee on the quarantine service is composed of former Lieutenant-Governor Robert Luce, chairman; Magnus W. Alexander of the General Electric Company, who served last year on the State Commission on Pensions; George W. Franklin of the Walker-Gordon laboratory; Irving B. Howe of A. H. Howe and Sons, shoe dealers; Demarest Lloyd of the Boston Journal; and Hugh D. McLellan, lawyer.

On Thursday of last week, January 28, this committee held a public hearing which all interested persons were invited to attend for expres-

sion of their views or to submit supplementary information. The committee had before it the stenographic records of the hearing of the City Council on January 1 and other data hitherto presented. Although the subject of maritime quarantine has previously been considered in the JOURNAL, the question is of such importance that its further discussion at the present time seems desirable.

Maritime quarantine is about as old a subject as history. In general but little thought is given to it outside of those directly concerned, except when some epidemic occurs, or as recently, when the City of Boston discussed the advisability of turning the local quarantine station over to the Public Health Service. The expense of maintaining a model quarantine station is considerable and largely has to be borne by the taxpayers of either city, state or nation.

This country is a union of states, and for the common welfare a central form of representative government exists, with certain fixed powers. Each unit or state also has recognized rights. One of the rights of the national government is to regulate or restrict commerce with foreign countries, and in that the state must subordinate itself to the nation.

In 1893 Congress passed certain quarantine laws and designated the manner in which they should be carried out. It was declared unlawful for any vessel from a foreign port to enter any port in the United States except in accordance with the provisions of this act and with such rules and regulations of state and municipal health authorities consistent with this act. A penalty is provided for violation of same.

It is generally accepted that among intelligent people, the least governed the better. International or interstate quarantine is a matter bound to interest the country as a whole, for any port of entry may distribute people to every state in the union or to adjacent countries with whom we have treaty obligations, including certain sanitary protection.

Hence we find that the United States passes a national law and at the same time makes provision for any state or municipality to work its solution in its own way as long as the letter of the law is carried out. Further, there is nothing to interfere with the state adding such rules as it sees fit for local safety. For example, every quarantine station would be required to detain a case of bubonic plague and clean up the ship, but would not be required to do the same

with a case of measles or scarlet fever. The latter type of cases would be provided for under local rules.

Under the same Act of Congress an organized branch of the federal service was authorized to carry out these acts, namely, the Marine Hospital Service, now the Public Health Service, and it was provided for the Surgeon-General of that service under direction of the Secretary of the Treasury, to coöperate and aid state and municipal health boards in the enforcement of rules and regulations laid down by the Secretary.

In looking over the regulations issued in 1910 may be found sections explaining the above in detail. Pages 1 to 14 relating to regulation of foreign commerce by the government, show how local health boards must be familiar with federal law and enforce the same; how, in case of failure on the part of local health authorities to enforce the law, the United States can insist on a federal officer signing health certificates before a ship can enter a custom house, which means permit to discharge passengers, crew, and cargo.

These regulations are being constantly changed to facilitate commerce as new discoveries are being proven as to the transmission of disease. Also the government is being constantly informed through medical officers stationed at our consulates in foreign countries or by the consuls themselves of the sanitary conditions and existence of epidemic disease throughout the world. This information is distributed by the Public Health Service to all concerned.

The press inference is that it would be detrimental to local business to change from local to federal control for the following reasons: The port would be closed from sunset to sunrise. Ships from Canadian ports would be subject to delays that they now escape by being allowed to pass without stopping, regardless of time. Government officials with attendant red tape and, someone added, gold lace, would tend to delay clearance. In case of doubt decisions could be more quickly given than to have to wait an opinion from Washington.

On the other hand, it must be remembered that local officers have to conform to federal law and said law must have provided for these privileges or local officials might be accused of violations. As a matter of fact, the local men have always been efficient in this matter and the regulations provide under certain circumstances for ships to be passed after dark and for permits for

ships from adjacent territory, hence there can be no suspicion of special privilege. The fact that a large proportion of arriving passengers are destined to points outside the state brings up the question whether or not the local community or the nation should bear the expense.

The commercial world is moving steadily forward and today sailing ships are almost a thing of the past, steamers having taken their place. This is important as changes in structure and speed of ships affect quarantine problems. Sailing vessels were usually long enough at sea to cover the incubation period of disease and were easy to disinfect, their greatest danger being the carrier of disease in apparent good health. Steamships cover the route more quickly, are more difficult to disinfect thoroughly owing to their more complicated structure and may easily arrive with passengers or crew in the incubation stage. The danger of port infection always has to be considered as it depends on a knowledge of sanitary waterfront conditions of the port cleared as well as entered. For example, a plague infected rat escaping a ship in Boston might be a far more serious matter than the same event happening in some of the European ports.

Shipping firms are naturally interested in seeing that they have as little red tape as possible in clearing or entering their ships. Chambers of commerce are anxious that their cities may offer every facility for the landing of passengers and cargo in order that local commerce shall increase. They may feel that it is easier to do business with officials they know and who in turn are familiar with local conditions and problems. They want prompt decisions and officials interested in local welfare.

There is no known reason why the federal government cannot meet the local authorities and arrange to keep a certain number of local men in permanent employ to see that local interests are best served in compliance with federal regulations. The objection to the chief being in Washington should not be a stumbling block, for there is nothing in the law or regulations that prohibits officers in charge of quarantine stations having or using such authority as would cover all ordinary problems or emergencies. The objection made to gold lace seems largely due to military semblance and the natural opposition to military government incompatible with a republic. The Public Health Service is not a military service but a civil organi-

zation in which part of the officers are commissioned by the President and part appointed by the Secretary of the Treasury under the rules and regulations of the United States Civil Service Commission. It may better be considered a sanitary police organization, a civil organization charged with the administration of laws relating to public health but without military rank or power. It is the nearest thing we have to a National Board of Health. There is no reason why it should not be conducted on broad business lines and appoint such officers as are best qualified for local needs. One of the best things that could happen would be for Congress to recognize it as a beginning of a National Department of Health and place or reorganize it on a liberal civil service basis. If this service is feared for any good reason by the commercial interests it is time it was reorganized on such a basis that it would be welcomed.

In an organized service with the functions of the Public Health Service a distinctive uniform is necessary for certain work, to distinguish grades, for discipline, and identification. For this purpose a simple uniform ought not to be difficult to devise. The uniform of the New York State Quarantine Service which is of a decided distinctive type has never yet been the cause of delay or complaint of delay in the work.

To sum up, there is nothing under the law which local officials can grant but what the federal officials can grant. It is a question whether the community prefers to pay the cost of maintaining a station for emergency, whether it would be better for the commercial and shipping interests to have local officials or federal officials administer the federal law, and whether the large interests of public health are not to be regarded above all local and personal considerations.

At a meeting of the City Council on Jan. 30 the proposed ordinance, effecting the quarantine transfer, was rejected without prejudice, in order that the matter may be brought up as new business before the new Council next week.

A CAREER OF PROFESSIONAL AND PUBLIC SERVICE.

On the first of February, Dr. John Hildreth McCollom retired after a service to the City of Boston in various medical capacities for forty-two years, the past twenty years of which were

spent at the Boston City Hospital. During these years he has made a notable record of professional and public service, and his retirement from more active participation in the administration of the hospital is an important loss to that institution.

After serving throughout the Civil War as hospital steward in the Thirtieth Regiment of Massachusetts Volunteer Infantry, Dr. McCollom first established his connection with the Boston City Hospital as house officer in 1868. In 1872 he became assistant to the city physician of Boston and served in that capacity until 1881 when he became himself city physician. In this capacity he served the public faithfully and efficiently until 1895, when he was appointed resident physician of the newly opened South Department. Here he served until 1909, acting since 1900 as physician for infectious diseases. It was during this period that he made his most valuable contributions to medical science.

Dr. McCollom's contributions to medical literature began early in his career. His first articles on "The Use of the Obstetric Forceps" and "The Smallpox Epidemic in Boston," were published in this JOURNAL in 1882 (Vol. 107, page 266 and 344 respectively). Following these the bibliography of his publications forms an important list of over thirty-five titles, covering a wide range of medical and surgical subjects. Most noteworthy of all these are his contributions on diphtheria, representing the results of his epoch-making work at the South Department. At the time when Dr. McCollom took charge of this department the mortality rate from diphtheria was 18 per 10,000 of population and nearly 50% of those infected. This was just before the introduction of intubation and antitoxin. It was the great achievement of Dr. McCollom by introducing these measures, not without opposition, and by the persistent efficiency of his own watchful professional care, to reduce the incidence and mortality of diphtheria almost immediately to their present low rate. Our feeling of security against this frightful scourge of humanity is now so familiar and easily assumed that we are prone to forget how great a service this was to mankind and to the progress of medical science. Dr. McCollom has won international recognition for this and for his similar work in the suppression of scarlatina, as evidence of which he was chosen in 1908, from among the entire medical profession, to write the chapters on

diphtheria and scarlet fever in Osler's "Modern Medicine." As city physician and as superintendent of the South Department, Dr. McCollom put into effect in practice the modern methods in control of contagious infections, so that since the opening of the South Department in 1895 there has been no general epidemic of scarlet fever in Boston comparable with those in previous years. The statistics of these diseases are modestly but eloquently presented in a series of graphic charts published by Dr. McCollom in 1914.

Upon the retirement of Dr. Rowe in 1909, Dr. McCollom became superintendent of the Boston City Hospital and for the past six years has displayed in that office the same zealous efficiency of public service that he showed as city physician and at the South Department. This period has been marked by important progress in the development of the hospital in which Dr. McCollom has had a prominent and guiding part. No detail of administration was so minute as to escape his watchful oversight. His standard of fidelity in the littlest things of public service was of the highest. To the discerning eye evidence of this is patent in every aspect of his work,—in the painstaking care, for instance, of his annual reports and hospital statistics. In his last report (the fiftieth of the hospital) is a diagrammatic table illustrating the percentage distribution of funds in the administration of the hospital, a diagram requiring much pains and labor for its preparation, and presenting results of important value to professional hospital administrators. Dr. McCollom was not only a public hygienist in advance of his time but established a standard of honorable fidelity in the administration of public funds which might worthily serve as an exemplar to others in public service.

Dr. McCollom has been fortunate in that his work has been genuinely appreciated by those of his own time and generation. In accepting his resignation as superintendent, the trustees wrote in part as follows:—

"The trustees are exceedingly sorry that your health has compelled you to take this step. They are reluctant to part with an associate with whom they have enjoyed such long and pleasant relations, and one whose unflagging zeal and earnest and untiring efforts for its welfare have contributed very much to the upbuilding and high standing of the hospital. But above all else stands the record of the great work you

have done for the South Department, which will be a monument to you more enduring than bronze or stone. Your unfaltering faith and courage in the use of antitoxin, which has so marvellously decreased the death rate from diphtheria, has saved to the world many thousands of useful lives and a grateful public will ever hold your name in high appreciation and gratitude for your noble services and research. After forty-two years of faithful service for the city of Boston, you have the consciousness of having achieved and merited a position that places you in the front ranks of the benefactors of mankind. In your retirement you carry with you the well wishes and high commendation of the trustees and the public. The trustees extend to you their sincere sympathy and the hope that a well-earned rest may restore such measure of health as to enable you to pass many years in comfort and enjoyment."

Dr. McCollom's contributions to medical science have also been abundantly recognized by his colleagues, and as emeritus professor of contagious diseases in the Harvard Medical School, he holds a position at the head of his special department of medicine.

It is a matter of the greatest good fortune for the community and the profession that Dr. McCollom's withdrawal from the hospital will leave him free to continue in private the study and practice of his specialty. The most cordial esteem and regard of the profession follow him with wishes for continued health and activity.

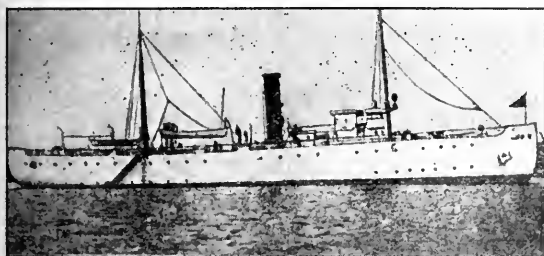

His has been a long and honorable career of professional and public service whose ripest and most honored years are yet to come.

A HOSPITAL SHIP FOR DEEP SEA FISHERIES.

In the issue of the JOURNAL for November 23, 1911, we published an editorial on "The Romance of Medical Relief at Sea," describing the plan, initiated by Drs. L. L. Williams and T. W. Salmon to provide a hospital cruiser to patrol the deep sea fisheries of our shore and carry first aid to the sailors who are endangering their lives in the common service. In 1912 a bill aiming to embody this project in legislation was introduced before the National Congress by Representative Gardner, asking an appropriation of \$50,000 for the purchase of such a craft and for a suitable annual appropriation for its maintenance. This bill was discussed in

Congress for over a year, was approved and advocated by numerous local and national bodies and was warmly championed by individuals, among them Dr. Horatio R. Storer and other physicians. Notwithstanding this, probably for political reasons, the bill, after being approved in committee and reported to Congress, was finally defeated in 1913. The project, however, was not at an end.

In the summer of 1914, Mr. Gardner obtained an amendment to the pending revenue cutter bill permitting the Secretary of the Treasury to fit out a United States revenue cutter to serve as a hospital ship in the deep sea fisheries off the New England and Newfoundland coasts. The *Androscoggin* was selected and equipped

THE ANDROSCOGGIN.

for this purpose and on December 22 was assigned to the Boston and Gloucester fishing fleet from January 1 to February 20. Capt. W. E. W. Hall is in command of the vessel and Dr. O. H. Cox of the United States Public Health Service has been detailed to take charge of the medical department. The equipment of the ship for medical and surgical purposes has been thorough.

"Three large rooms have been set aside for the hospital quarters. One is a sick bay with six sanitary cots, another is the isolation ward, with two cots, where contagious cases found among the fishermen will be cared for, and the third or centre room, consists of an up-to-date operating room, patterned after the hospitals on battle-ships. There is an operating table, water sterilizing tanks and basins, surgical instruments and in fact all the paraphernalia found in a hospital."

The route of the *Androscoggin* on its cruise comprises the fishing territory off the entire coast of northern New England and the Provinces, including Brown's bank off Nova Scotia and the Banquereau and Sable Island banks to the eastward. The vessel sailed from Boston early in January and on January 7 left Gloucester for her initial cruise. In the early days of her ser-

vice she seems amply to have justified the expectations of those who have consistently urged the necessity of such a service. Within a week the vessel was able to transfer from a fishing schooner to hospital at Halifax a patient with appendicitis in urgent need of operation, and numerous minor cases were treated aboard the *Androscoggin* or by boarding parties on their own ships. Later, when the Belgian relief ship *Camino* was disabled, the *Androscoggin* aided the British steamer *Kanawha* in conveying her safely to port. It is a matter of great satisfaction to physicians and to all interested in problems of medical relief, that it has at last been possible to establish a service so urgently needed. The success of this first six-weeks' cruise of the *Androscoggin* should lead to the extension of the plan for such service in the future, a service in which the United States has hitherto been discreditably inferior to Great Britain, France and other civilized nations.

THE NURSING QUESTION.

A BILL is now before the Massachusetts Legislature to amend the requirements for nursing to the following effect:

"Applicants must show the usual qualifications as to age, character, etc., and must have received a certificate of graduation from a training school for nurses, considered efficient by the board, etc., etc. Applicants for limited registration under this act, who shall furnish proofs as to age, character, etc.....but who cannot qualify as graduates of approved training schools for nurses...shall be examined by said board, and if found competent to care for cases which do not require expert services, shall be registered with right to use the title of household nurse, and shall receive a certificate in testimony thereof, etc. Nurses registered with the title household nurse, shall not care for the major surgical cases, nor make internal obstetric examinations....."

"After January first, in the year nineteen hundred and sixteen no person shall engage in the work of nursing for hire in this commonwealth unless he or she has become registered in accordance with the provisions of this act."

"The board shall have authority under this section to investigate at any time the training schools for nurses in this commonwealth for the purpose of determining their fitness and efficiency as shown by their general equipment, by the character, the methods and the extent of in-

struction given. For the purpose of conducting this investigation the board may employ a person legally entitled to the title of registered nurse."

It would appear from a paper entitled, "Some Problems in Relation to Nurses' Training Schools," read by Dr. Charles Stover before the New York State Medical Society, that only ten per cent. of the nursing outside of hospitals in the state of New York is done by graduate nurses. There are no figures to show that this proportion is different in Massachusetts. In other words, nine-tenths of the people,—probably those who cannot afford to pay the minimum price of twenty-one dollars a week are a considerable proportion—must get along without trained nursing when they are sick. Although provision is made in the bill for "household nurses," legislation is asked to prohibit nursing for hire unless registration has been obtained.

At the meeting of the New York society at which Dr. Stover read his paper a committee was appointed consisting of Dr. Stover, an ex-president of the society, Egbert LeFevre, dean of the University and Bellevue Medical College, Alexander Lambert, professor in Cornell Medical College, and Roswell Park, the eminent surgeon. The report of this able committee should cause our legislators to consider seriously whether we in Massachusetts may not adopt the same conclusions. The report was in part:

"It is a fair conclusion that the standard for entrance in New York is too high for practical results. . . . It is more important that the people have small hospitals than that a few highly trained nurses obtain the thus-far little coveted title of R. N. . . . Meanwhile your committee is of the opinion that the State should recognize the nurse problem as an experimental one, to be regulated at present by wise administration rather than by legislation."

After all is said, the health of the public under the present laws is in the hands of the physicians who have been registered by the Commonwealth and the responsibility is theirs and not that of their assistants, the nurses. If the physician finds his assistant unsatisfactory he can procure another, adapted in training, personality and pay to his patient's requirements. Perhaps in the future the nursing profession may provide trained services for all of the people for good pay, for small pay, or for no pay at all, just as now the medical profession furnishes

skilled care to all the sick. When this time arrives, if it does, it may seem best for the State to limit nursing to those who are registered. Conditions at present do not justify such a course. That the Board of Registration of Nurses should have supervision over the training school for nurses is a debatable point and does not correspond with the practice in the case of the Board of Registration in Medicine and the medical schools.

CONGENITAL PYLORIC TUMOR.

In an article printed elsewhere in this issue of the JOURNAL, Dr. Charles L. Scudder presents and emphasizes an important differential classification of cases of congenital infantile pyloric stenosis. The obstruction in these cases may be either functional or organic, it may be due either to muscular spasm or to the presence of an actual tumor impinging upon the lumen of the pylorus. That true and uncomplicated pylorospasm may exist there can be no reasonable question. In babies presenting this condition, the symptoms are not pernicious, they are variable, and are characterized chiefly by intolerance of the stomach for the total amount of food which it ought normally to contain at the given age, though on lesser amounts of somewhat stronger food the nutrition can be fairly well maintained. On the other hand, babies in whom the obstruction is due to pyloric tumor are intolerant of all food, and present a fairly invariable train of fatally progressive symptoms. The most important point, therefore, in the diagnosis of cases of congenital infantile pyloric stenosis is the early and accurate differentiation of these two classes of cases. This may most effectively and reliably be accomplished by means of the bismuth meal x-ray.

It has been maintained by many that in cases of obstruction due to pyloric tumor there is present also an element of pylorospasm. This statement seems to be fairly disproved by the series of cases reported by Dr. Scudder from his personal observation, and collected by him from the literature and from the personal communications of other surgeons, in which bismuth meal x-ray or autopsy has shown the persistence of absolute pyloric obstruction by tumor following symptomatic relief of the condition by posterior gastroenterostomy. Dr. Scudder speaks with authority on this subject by virtue of his extensive and

successful experience in the treatment of such cases. For the general practitioner, the most valuable lesson to be derived from this consideration is the crucial importance of the prompt and accurate differential diagnosis of all cases of congenital pyloric obstruction before it is too late for surgical intervention to afford prospect of life-saving relief.

MEDICAL NOTES.

EUGENIC BILL IN INDIANA.—Report from Indianapolis states that on January 21 the Indiana Senate passed a bill requiring that all persons before obtaining a marriage license must present a satisfactory certificate of health from a physician. The bill awaits action by the house of representatives.

PATHOLOGIC PICTURES IN NATURAL COLORS.—On Friday and Saturday of last week, January 29 and 30, at an exhibit of x-ray materials in Atlantic City, N. J., there was shown a valuable collection of pictures of pathologic specimens in natural colors, made by means of the new kodachrome plates. This is the first public exhibit of work of this character and the possibilities suggested by this method of reproducing pathologic material are of distinct interest to physicians.

BRITISH NEW YEAR'S HONORS.—Among the recipients of British New Year's honors recently announced are, as usual, several physicians. Sir William MacGregor, G. C. M. G., C. B., is appointed to the Privy Council, Surgeon Major General Eugene Fiset of Canada, is created C. M. G., and the order of knighthood is bestowed on Perceval Aleyne Nairne, Chairman of the Committee of the London School of Tropical Medicine.

NEW YORK DEATH RATE DECLINES.—The mortality during the past week was noteworthy because of the extremely low point which it reached as compared with that of the corresponding week in 1914,—13.10 last week as against 14.6 in 1914. Inasmuch as the mortality of the previous weeks of last year was relatively high, this drop for the city is very welcome. Taking into consideration the increase of the population, the weekly rate during the week just ended shows a decrease equivalent to 171 deaths. The deaths from influenza numbered approximately the same as during the same week in 1914; on the other hand the deaths from organic heart diseases, diseases of the digestive system, pulmonary tuberculosis,

Bright's disease and nephritis, and diseases of the nervous system were considerably fewer.

The number of deaths from pneumonia, while much higher than in the corresponding week in 1914 was considerably below that of the week ending January 16th, 1915. The mortality from the infectious diseases, especially measles and diphtheria was very much below the average.

Viewed from the point of age, the decreased mortality was apparent in all the age groupings of the population.

The death rate for the first four weeks of this year was 14.32 per 1000 as against 14.62 per 1000 for the corresponding period in 1914, a decrease of .31 of a point.

EUROPEAN WAR NOTES.—Report from Budapest states that on January 2 Dr. William Crookston, the new director, and Dr. Henry Day, the new assistant director, of the American Red Cross Hospital at Budapest, arrived in that city from New York by way of Genoa. Dr. Charles MacDonald of Salem, N. J., the former director, and Dr. Cary A. Snoddy of Knoxville, Tenn., the new director of the American Red Cross Hospital at Vienna, also arrived at Budapest on the same day.

It is announced that Mr. William Lindsey of Boston, has promised to give, if necessary, \$10,000 to pay the expenses of the Harvard Medical School unit which it is planned to send to the American Ambulance Hospital at Paris on April 1. This unit will have charge of wards aggregating one hundred and fifty beds.

An official report of the American Red Cross Society published on January 22, records the activities of that organization from August 1, 1914, to January 1, 1915. During this period a total fund of \$1,188,112. was collected by the Red Cross. Up to January 9, \$760,510. of this fund has been expended in the maintenance of forty-five surgeons and one hundred and fifty nurses on war duty in Europe.

"By March the six months' duty, which each member of the various units agreed to give the Red Cross, will have expired, and those who desire to return to this country will be allowed to do so, other surgeons and nurses being sent to Europe to take their places.

"The report shows that up to January 9 the Red Cross had shipped to Europe 772,900 pounds of medical cotton, 802,400 yards of gauze, 709,000 assorted bandages, 3168 rolls of adhesive plaster, 13,965 pounds of chloroform and ether, 77 cases of drugs and medicines, 35 cases of instruments, 20 United States army field medical outfits, 15,000 doses typhoid prophylactic, 10,000 tubes smallpox vaccine, 50,000 doses tetanus antitoxin, 9,500 blankets, 2,211 shawls, 516 coats, 1,740 sweaters for women and children, 10 barrels of alcohol, and 2,638 cases of miscellaneous supplies."

The French Red Cross, consisting in reality of three affiliated societies, has been taking an active part, in conjunction with the French War Office, in the care of wounded soldiers in the north of France. "At the beginning of the war this society established 93 dressing stations, 83 dispensaries and 35 canteens at railway stations. The principal work since undertaken by the society has been the preparation of auxiliary hospitals; it has organized altogether 771, which contain now 56,579 beds. To bring the wounded to these hospitals, however, it possesses only 32 automobiles, which are stationed for the most part at Paris, Amiens, Creil, and Rheims."

On Jan. 30 the total of the New England Belgian relief fund amounted to \$186,276.41; the Massachusetts Red Cross fund to \$106,997.28; the New England Jewish relief fund to \$29,727.92; and New England British relief fund to \$17,506.82; the New England Polish relief fund to \$14,961.67; and the Russian relief fund to \$10,674.00.

In New York the following committee has been appointed to organize and raise a Serbian relief fund: Willard Straight of J. P. Morgan and Company, Mrs. Edward Hewitt, Prof. M. I. Pupin of Columbia University, Dr. Albert Shaw, Mrs. Lawrence Elliman, Mme. Grouitch, Mrs. Ethelbert Nevins, Mrs. John L. Griffith and Miss F. Hastings, secretary.

BOSTON AND NEW ENGLAND.

HOSPITAL CONCERTS FOR FEBRUARY.—The concerts of the Boston Hospital Music Fund for February have been announced as follows:—

Feb. 7 Perkins Institution for the Blind, Watertown.

Feb. 14 and 21 Boston City Hospital.

Feb. 23 Cullis Consumptives' Home.

Feb. 28 Cambridge Homes for the Aged.

MASSACHUSETTS HOMEOPATHIC HOSPITAL.—The annual meeting of the corporation of the Massachusetts Homeopathic Hospital was held in Boston on January 26. The present officers were reelected. Owing to the unusually large number of free patients last year, a deficit of \$20,000 was announced in the financial report. Edward H. Mason, the president, reported that during 1914, 6,489 patients were treated in the main hospital, and in all departments 23,260, an increase of 808 over 1913.

At the Haynes Memorial department for contagious diseases, 757 patients were treated, 300 more than in any other year since the opening of the department in 1908.

BROOKLINE FREE HOSPITAL FOR WOMEN.—The recently published thirty-ninth annual report of the Brookline (Mass.) Free Hospital for Women records the work and progress of that institution for the year ended October 1, 1914. During this period the total number of patients operated

on was 705, an increase of 23 over the previous year. In the out-patient department there were 6,190 consultations and 1,350 new patients of whom 742 were referred to the main hospital. A class of twelve nurses was graduated from the Training School. The report is illustrated with several full page plates representing Potter ward, the hospital building and a portrait of the late Dr. William H. Baker, founder of the Hospital, of whom an admirable obituary is presented in the report by Dr. William P. Graves.

PORTLAND BOARD OF HEALTH.—The recently published twenty-seventh annual report of the Portland (Me.) Board of Health records the activities of that body for the year ended April 1, 1914. During this period the city suffered from a small epidemic of forty-seven cases of small-pox which was efficiently controlled and terminated with no deaths. The total number of deaths during the year was 1,059, of which 121 were from pneumonia, 109 from nephritis and 86 from tuberculosis. The total number of births was only 1,262.

DIPHThERIA IN HOLYOKE.—The latest public health bulletin issued from the office of the Massachusetts Commissioner of Health, presents the following statement relative to a small epidemic of diphtheria which occurred in Holyoke, Mass., during the late summer and fall of last year:—

"Twenty-nine cases of diphtheria were reported by the Holyoke Board of Health, the first on August 20 and the last on November 4. Since November 4 no cases have been reported from the Springfield district. The 29 cases occurred in 20 homes. In 15 families there was one case each; in two families, two cases each; in two families, three cases each; and in one family, four cases. The 10 houses were apartment houses. The ages of the patients varied from two to fourteen. The epidemic occurred soon after the opening of the Springdale School on September 8.

"There were three deaths, one in October and two in November.

"The probable cause of the epidemic was some mild unrecognized diphtheria bacillus carrier. It could not be ascertained whether the infection actually started within or without the school; that it spread among the school children, however, is a known fact, and undoubtedly by direct contact."

EPIZOOTIC OF FOOT AND MOUTH DISEASE.—On January 22, the federal quarantine for foot and mouth disease in Massachusetts was raised from the counties of Barnstable, Berkshire, Dukes, Franklin and Nantucket. The only territory in the State where the disease now exists is at Dracut and in the vicinity of Rehoboth and Swansea. Portions of the counties of Bristol, Essex, Hampden, Hampshire, Middlesex,

Norfolk, Plymouth, Suffolk and Worcester are still, however, considered exposed areas.

In Connecticut the quarantine was, on the same day, raised from the counties of Fairfield, Litchfield, Middlesex, New London, Tolland and Windham, but portions of the counties of New Haven and Hartford are still considered as exposed area.

In Rhode Island the quarantine was raised from the counties of Bristol and Washington, but portions of the counties of Kent, Newport and Providence remain as exposed territory. Report from Providence on January 22 stated that on that day two more infected herds were discovered, one at Pawtucket and one at Pocasset.

MENINGITIS AND POLIOMYELITIS IN MASSACHUSETTS AND NEW YORK.—The weekly report of the United States Public Health Service for January 22, states that during December, 1914, there were in Massachusetts twelve cases of cerebrospinal meningitis and six of poliomyelitis, and in New York, twenty-seven cases of meningitis and sixteen of poliomyelitis.

THE SANITATION OF CHINATOWN.—The Boston Board of Health has recently made an active investigation of sanitary conditions in the Chinese quarter of this city and has ordered extensive changes and improvements in that district. The alterations required are indicated by the following regulations which have been issued by the Board:—

"Every building must be equipped with two ways of entering and leaving, one in front and one in back. All sewer pipe openings must be permanently closed. By means of such openings in cellars, it is claimed, gamblers have been able during police raids to throw gambling implements wholesale into the sewers. All swinging gas fixtures must be replaced with stationary fixtures. The fire sprinkler system must be installed in every building occupied by eight or more families. Every basement must be ventilated to the satisfaction of the Health Board. Every basement must have proper exits and entrances. All stairways must be thoroughly repaired. All fire balconies must be repaired, and buildings lacking them must immediately install them."

MILK AND BABY HYGIENE ASSOCIATION.—The Boston Milk and Baby Hygiene Association has recently issued a small book to mark the close of the sixth year of its activities.

"From 1906 to 1910 there was an average death rate of 133 out of every 1000 babies born. Since the organization of this association the rate has steadily decreased until it was reported in 1914 the infant mortality was reduced to 100 out of 1000. It is hoped that in the coming year this rate may be even more decreased through the work of this society.

"During the past year the association provided medical supervision and nursing service

for 4,097 babies, which is over one-fourth of the babies that are born here every year. It also cared for 20 per cent. of the babies that were under one year old.

"Free advice was given at 655 medical clinics, at which the attendance numbered 19,673. This is an increase of 43 per cent. over last year's work.

"Under the auspices of this society 12 milk stations have been maintained in the poorer districts of the city, where mothers could obtain tested milk at cost. The mothers in many homes were instructed by 14 specially trained nurses employed by the society. These nurses made 50,221 visits to homes and demonstrated to the mothers and children in the neighborhood of the milk stations through the 'Little Nurses' Club, the care of babies.

"Besides this work, the society has conducted an active campaign for spreading knowledge of the prevention of sickness and the proper care of babies.

"The cost of maintaining this work is about \$25,000 a year. The Association has no endowment and the work has had to be done by means of public subscription. It is interesting to note that \$10 provides medical and nursing supervision for one baby for nine months and \$20 will care for two babies for one year. Fifty dollars pays for the expenses of a milk station for one week which has the registration of 2,000 babies. One thousand dollars provides a nurse and incidental expenses of one milk station for one year, and \$300 provides service for one station through the hot weather.

"The headquarters of the Association are at 26 Bennet street. The officers for the coming year are: Chairman, Edward R. Warren; secretary, Michael M. Davis, Jr.; treasurer, Charles E. Mason; director, George R. Bedinger; medical directors, Drs. Arthur A. Howard and Harold A. Gale."

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Jan. 26, 1915: Diphtheria, 79, of which 6 were non-residents; scarlatina, 89, of which 15 were non-residents; typhoid fever, 8; measles, 60; tuberculosis, 54, of which 1 was non-resident. The death-rate of the reported deaths for the week was 15.25.

1. Porter's conclusions from experimental and clinical data are that injections of boiling water into the thyroid gland should be substituted for the so-called medical treatment in patients with small thyroids and moderate symptoms of hyperthyroidism. This method is also peculiarly well adapted to the treatment of patients with moderate or severe symptoms and relatively small glands, and especially to cases wherein the hyperplasia is circumscribed. It is, therefore, well adapted to the treatment of patients who have had a lobectomy done and are still suffering from symptoms of hyperthyroidism with hypertrophy of the remaining lobe. Patients with large goiters and extreme symptoms of hyperthyroidism should be treated with the injections until they become safe surgical risks and then have the gland removed. Boiling water injections are not recommended in non-toxic goiter.

2. Clopton's article is beautifully illustrated and of distinct interest. It is a careful study.

3. Rodman, drawing from his own experience and that of other operators, is of the decided opinion that if the ulcer or ulcers are situated at or near the pylorus, as they are in about 80% of all cases, and the pyloric end of the stomach and proximal portion of the duodenum can be easily mobilized, pylorctomy, which gets rid of the existing ulcers, and prevents future ones to a large extent, removing as it does, four-fifths of the ulcer-bearing area, is certainly the operation of choice. The frequency with which hemorrhages, perforation and cancer, especially the latter, follow gastroenterostomy, show it to be wholly inadequate. Moreover, the radical operations of excision and pylorctomy are only slightly more dangerous, while far more beneficial in every way than gastroenterostomy.

5. Buford in an interesting article shows that in certain districts like Chicago, where sewage polluted water is used for drinking purposes, there is a frequent occurrence of goiter among children. This condition may also result from focal infections such as occur in tonsils, adenoids, and necrotic teeth.

9. Runyan states that many x-rays are often necessary to make a diagnosis of dislocated carpal semilunar. Closed reduction can be accomplished in about half the cases and should be tried irrespective of the length of time since the dislocation occurred. Open reduction is preferable to excision.

10. Campbell reviews the signs and symptoms of the different kinds of benign tumors of the stomach and describes a very interesting case of his own of papilloma of the stomach relieved by operation.

4. Overend presents a long and elaborate paper on incipient tuberculosis in school children from the point of view of the roentgenologist. He limits his discussion to children between the ages of 5 and 15, when the tuberculous process tends to become localized within the ducts and glands of the lymphatic system of the respiratory organs. This is practically the time of school life. He describes the radiological appearance of a healthy child's chest, and then takes up the anatomical and pathological considerations. He divides the bronchial glands into four classes: (a) tracheo-bronchial, (b) bifurcation, (c) hilum, and (d) pulmonary glands. The exact location of these glands and their pathological consideration, he describes.

He then discusses the channels of infection and dissemination; and among various possibilities, includes: 1. Caseation of glands. 2. Caseous pneumonia. 3. Eruption into a bronchus. 4. Eruption into a blood vessel. 5. Lymphatic dissemination.

The clinical symptoms and signs are at first obscure and indefinite, and due to a slow and chronic absorption of the products of bacillary metabolism and to the compression exercised upon adjoining structures by enlargement of the glands. He discusses these

signs and symptoms in detail. He devotes a very short space to the physical signs.

He then takes up the radiological examination of the patient. The radiologist, in his opinion, should endeavor to decide as to: 1, Presence or absence of disease. 2, Its activity or latency. 3, Whether it is open or closed. 4, The course of dissemination. (In the reviewer's opinion, the radiologist has a large task before him if he can correctly answer these last three questions.—J. B. H.) He presents a few illustrative cases.

The presence of the following five conditions he believes enough to strongly suspect enlarged bronchial glands, probably of tuberculous origin: 1, Intermitting sudden cough in the absence of cases of pertussis. 2, Wasting, pallor, and tiredness. 3, A sub-febrile temperature, rising occasionally to 100°. 4, The presence of capillary veins and a growth of hair over the upper thoracic spines. 5, The absence of any obvious disease. 6. PHILLIPS, L. *Is Emetin Sufficient to Bring About a Radical Cure in Amoebiasis?*

1. Bowlby gives an interesting account of his work during the past three months with the British army in France. He describes in detail the functions of so-called "clearing hospitals." Such hospitals are essentially mobile units connected with the army. He describes the class of cases received and the general methods of treating the wounded.

5. Bassett-Smith presents an interesting description of kala-azar or parasitic splenomegaly and allied infections. His article is a general summary of these conditions, the methods of diagnosis employed, etc., although presenting nothing especially new. [J. B. H.]

11. *RICHARDS, D. T. *Some Lung Affections in Influenza.*
12. DRINKWATER, H. *The Longevity of Eminent Medical Men.*

5. Wynter discusses in a very general way some obscure cases of carcinoma in which the symptoms

were very obscure, chronic, and generalized. He discusses the importance of these general symptoms in the diagnosis of this condition.

6. Handley discusses the question of carcinoma of the breast following trauma, and presents evidence for and against any relationship between the trauma and a subsequently developed cancer.

7. Rivière in a very general way discusses the pneumothorax treatment of phthisis, and presents various illustrative cases. On the whole, and in suitable instances, he is very favorably inclined toward this method of treatment. Suitable cases, in his opinion, are those who have had a thorough course of sanatorium treatment, and who seem, in spite of this, to be going down hill.

11. Richards, in a most interesting article, discusses some lung affections in influenza, with particular reference to migrating apical pneumonia. In regard to this, he quotes Dr. West as stating, "Influenza stands in no special relation to phthisis. . . though it greatly reduces the resistance of a body to the pneumococcus, it does not seem to do so in any special way to the tubercle bacillus." Dr. Richards agrees with this point of view, and finds that in only rare instances has tuberculosis developed after an influenza process of this kind. He presents various interesting cases showing that pneumonia due to influenza, and other pulmonary processes due to the same cause, must be regarded as serious conditions. Although he presents no exact bacteriological evidence to show that these cases were all due to the influenza bacillus, he apparently includes in this term "influenza" a variety of infection which in this country, for lack of a better word, we are apt to call "grip." 10. SCHWALBE, J. *A Letter from Ernst v. Bergmann from the Turko-Russian War of 1877.*
11. *SCHWALBE, J. *Salvarsan "Made in England."*

1. Jochmann reviews the history of tetanus, its mode of infection, its clinical course and its treatment. For the early laboratory diagnosis he advocates the injection of suspected material mixed with sterile pumice stone under the skin at the root of the tail of mice. The pumice acts as a foreign body and attracts the leucocytes, and usual pus organisms. In this way the oxygen is used up, anaerobic conditions are produced, and the tetanus organisms grow rapidly,

producing characteristic symptoms in two or three days.

For the cultural diagnosis of the disease, Jochmann uses for medium grape-sugar bouillon. The culture is made according to ordinary technic, and the surface is covered with sterile oil. The culture is heated to 70° C., which kills off any non-spore-bearing organisms. After this, the tetanus organisms grow at 37° in pure culture.

In the treatment of tetanus, Jochmann places great reliance upon active serum treatment. He gives 100 antitoxin units intraspinally every day or two as long as convulsions are present. At the same time he injects intramuscularly, near the wound, 100 units daily, and powders the wound with dried antitoxic serum. In this way he hopes to neutralize as much toxin as possible. Finally, on the first day of treatment, he injects 100 units intravenously.

Such active treatment has not had the brilliant results which follow the use of anti-diphtheritic serum. Nevertheless, Jochmann believes that the more energetic the anti-tetanic treatment is, and the earlier in the disease it is begun, so much more favorable are the results.

Jochmann mentions the magnesium sulphate treatment, but has had too little personal experience with it for a definite opinion as to its practical value.

For symptomatic treatment, Jochmann advises morphia and chloral in large doses and either alone or combined. The patients must be well fed. When unable to eat by mouth they must be fed by rectum or subcutaneously. For the latter purpose, Jochmann has given sterile oil in as large doses as 100 grams.

7. Foligan "Henning" is a preparation of powdered orange leaves made by the firm of Henning. Epstein has used it as a sedative in a series of cases. On the whole he feels that Foligan is valuable, yet he has met with several cases in which the drug appeared to have no action.

11. Schwalbe writes a bitter article commenting upon the fact that Burroughs, Wellcome and Company are attempting to obtain rights to sell their own new products under the names of salvarsan and neosalvarsan, thus encroaching upon the patents of Höchst. Schwalbe considers that such action is unjustifiable even in war, but believes that if the London firm undertakes the manufacture of salvarsan, the injuries produced by the new drug will produce a new "English" disease, and will leave a lasting monument in the English literature.

5. *FRIEDRICH, E. P. *Aural Problems in War Surgery.*
6. KÜMMEL, W. *Ear Diseases in the Field.*
7. STEIN, A. E. *Medical Photography.*

1. Czerny mentions the conditions under which tetanus will develop. Bullets rarely produce the disease, but more favorable wounds are those caused by shrapnel when large skin areas are laid bare. Prophylaxis is most important. Czerny advises prophylactic serum in any doubtful case. The best treatment is antitoxin, given either intraspinally, endoneurally, or intravenously. The most effective drugs to alleviate symptoms are morphia, chloral and paraldehyde.

5. Friedrich discusses in a general way the injuries to the ear which he has seen during the war and describes their treatment. Injuries to the external ear with indirect injury to the drum are common. One of the frequent diseases of the external ear

also is furunculosis. The middle ear may occasionally be wounded by stabbing, but more often by splinters of shot or by wounds of the skull. Acute otitis media develops among troops from time to time sporadically. The internal ear can be injured directly by bullets or stab wounds, and indirectly by detonation. The treatment is largely symptomatic, since it is difficult to treat these diseases satisfactorily at the front. [R. F.]

3. Since x-ray and sunlight stimulate the growth of epithelium so definitely in chronic ulcerative processes, Kromayer has used them for the same purpose in the treatment of wounds which present large ulcerated surfaces. He advocates small dosage of x-rays and states that any x-ray burn of the skin must be avoided. In using sunlight or carbon as a substitute, enough exposure is given to produce a slight erythema. On the whole, Kromayer believes that much time can be saved in the healing of wounds by the proper use of these rays.

6. Engel has undertaken to determine the amount of urine excreted by normal infants, the frequency of urination and how large are the individual portions excreted. The method of collecting the specimens consisted in connecting to the urinals used, electrodes, which in turn were attached to a bell. Thus when the subject urinated, a nurse was called, who recorded the time and the amount of urine. The amount of urine depended on the fluid intake. If an infant drinks 800 c.c. of liquid, normally about 500 c.c. of urine are excreted. An infant urinates between 20 and 30 times in 24 hours. Engel found that during periods of quiet, much less urine was excreted than during periods of muscular activity. Thus, when the child slept there would be no urine for two or three hours, while if the child were awake it urinated every few minutes. Finally, Engel found that the average amount of urine obtained at each emptying of the bladder was between 12 and 18 c.c., although in isolated cases 70 to 90 c.c. were recovered. The amount of individual specimens depended closely on the degree of muscular activity. [R. F.]

al experiments on the bones of 28 recently deceased human subjects. Of these, 15 were found completely sterile, in 2 the streptococcus was found and in 11 the staphylococcus. The subject is of importance in relation to homo-necro-transplantation of bone tissue.

[R. M. G.]

Miscellany.

REGULATIONS OF STATE DEPARTMENT OF HEALTH.

At the meeting of the Public Health Council of the State Department of Health on January 9, 1915, the following regulations were adopted, governing the appointment and promotion of district health officers, to be appointed within the provisions of Chapter 792, of the Acts of 1914.

1 Grades of District Health Officers. There shall be four grades of District Health Officers, viz: A, B, C, and D.

2 District Health Officers appointed only to Grade D. Candidates for the position of District Health Officer, after passing a successful examination, shall be eligible for appointment to Grade D, except in the cases specified in Section 14.

3 Form of application for appointment. Candidates for the position of District Health Officer must make application addressed to the Commissioner of Health in their own handwriting, asking permission to appear before the Board of Examiners. Candidates shall state their age, date and place of birth, present legal residence, names of colleges or institutions of learning of which they are graduates, date of graduation, and shall furnish testimonials as to their professional experience and moral character.

4 Age limit. No candidate will be eligible to appear before a Board of Examiners whose age is less than twenty-three years or more than thirty-six, except in the cases cited in Section 14.

5 Professional requirements. Candidates shall be graduates of an incorporated medical school or shall have had at least five years' experience in public health work and sanitary science.

6 Citizenship. All candidates must be citizens of the United States, and preference in appointment shall be given to residents of Massachusetts.

7 Physical examination. Candidates for appointment must pass a satisfactory physical examination before a Board of Examiners except as provided in Section 14.

8 Board of Examiners. The Board of Examiners shall consist of three or more members. These members shall be selected by the Commissioner of Health from the Public Health Council or other officials of the State Department of Health.

9 Scope of examination. All examinations of candidates for appointment as District Health Officers shall be conducted by a Board of Examiners and the examination shall include a physical examination and such oral, written and practical tests as the Board deems necessary in the subjects outlined in the succeeding sections. Experience and fitness shall also be rated by the Board of Examiners.

10 Subjects for written examination. All candidates for appointment must pass a satisfactory written examination in Communicable Diseases, Hygiene and Sanitation, Preventive Medicine, Vital Statistics, Pathology and Bacteriology.

11 Compensation. The compensation of District Health Officers shall be as follows:

Grade A.	\$3500.00
Grade B.	3000.00
Grade C.	2500.00
Grade D.	2000.00

12 When promoted. After five years' service in any grade the District Health Officer is entitled to examination to determine his eligibility for promotion to the next higher grade.

13 Examinations for promotion. Examinations for promotion shall be conducted by a Board of Examiners, who shall take into account the efficiency record of the candidate as well as his professional and physical fitness. Failing first examination a District Health Officer may be given a second examination after one year. Failing two successive examinations, such a District Health Officer shall be dropped from the rolls.

14 Exemptions in favor of candidates now in the service. Candidates for appointment as District Health Officers who are now (January, 1915) State Inspectors of Health in the service of the State Department of Health shall be exempt from certain provisions of these regulations, as follows:

- The age limit of thirty-six years is waived.
- If successful in passing the entrance examination they shall be eligible for appointment to Grade C, provided they have had five years' service as State Inspector of Health of the State Board of Health.
- They shall be given credit for service as State Inspector of Health of the State Board of Health in excess of five years in fixing the date of their eligibility for promotion to Grade B.
- If successful in passing the entrance examination with distinction they shall be eligible for appointment to Grade B and shall be eligible for promotion to Grade A after two years' service in Grade B.

15 Tenure of office. A District Health Officer may be removed from office by the Commissioner of Health because of failure to pass two successive examinations for promotion, or because of gross misconduct or inefficiency, but only after the accused officer has been furnished with a

copy of the charge made against him and given a hearing thereon by the Public Health Council.

It was voted to fix the date of the examination for Tuesday, February 16, and Wednesday, February 17, 1915, at 9.00 a. m., at the office of the State Department of Health, and it was further voted to require all applications for examination to be received in the office of the State Department of Health on or before February 10, 1915.

A. J. McLAUGHLIN, M.D.
Commissioner of Health.

THE AMBULANCE CONSTRUCTION COMMISSION.

THE present European war is the first in which field motor-ambulances have been extensively used. It was inevitable that many defects should be found in existing types, and in various quarters experts began to ask whether something could not be done to standardize the patterns and to improve the type. At the instance of Mr. Henry S. Wellcome, the founder of the Wellcome Bureau of Scientific Research, a Commission has been formed, and the names of members show at once that the matter is regarded as of first importance by those most intimately connected with the welfare of the wounded soldier.

Sir Frederick Treves, whose long experience and distinguished service specially fit him for the task, has consented to be the Chairman. The Admiralty is represented by the Director General of the Medical Department, R. N., while the Quarter Master General to the Forces and the Acting Director General, Army Medical Service, represent the War Office. The British Red Cross Society is, of course, represented by Sir Frederick Treves, and the St. John Ambulance Association by Sir Claude Macdonald and Sir John Furley. The remaining members are all experts. This Commission will first and foremost act as a judging committee for the award of prizes of the value of £2000 provided by the Wellcome Bureau of Scientific Research. These prizes are offered for the best designs of an ambulance-body which shall fit a standard pattern motor chassis for field motor ambulances. The last day for the receipt of competing designs is June 30, 1915. It is hoped that the competition will bring in a number of ingenious designs, from which the ideal field ambulance body will be evolved.

It may be asked why the competition is restricted to designs for a body and not for a complete ambulance including a chassis. The reason is that a chassis takes much longer to build than a body, and that, when war breaks out, it is impossible to get at short notice anything like a sufficient number of any one type of chassis.

On the other hand, a standardized body to fit any chassis of approved dimensions can be constructed in numbers at comparatively short notice. And a perfected body is badly wanted to ensure complete comfort for the wounded.

It is hoped that the information obtained by the competition, and in other ways, will be published in some permanent form, available for future reference. Probably in addition to one design of special excellence, there will be submitted various ingenious suggestions which may be incorporated in the pattern design approved by the Commission. For these, a portion of the prize-money has been set apart. The first prize is of one thousand pounds, the second of five hundred, and the third of three hundred pounds. All details of conditions may be obtained from the Secretary, the Ambulance Construction Commission, 10 Henrietta Street, Cavendish Square, London, W. The competition is open to citizens of all nations.

INSANITY IN MASSACHUSETTS.

THE recently published annual report of the Massachusetts State Board of Insanity records the work of that body and of the hospitals under its charge during the past year. The report shows that one out of every 271 persons in this Commonwealth is insane.

"The insane being cared for in state institutions number 13,497, an increase for the year of 396. The board has under its care 17,386 persons, of whom 14,122 are insane, 2513 feeble-minded and 624 epileptic.

"The capacity of the institutions is now 13,971, and this includes new accommodations for patients, which have recently become available. Notwithstanding this addition, there is, at the present time, an overcrowding of 231. As the Legislature of 1914 granted no appropriations for patients, there are no new buildings in the process of construction. It will thus be seen that, provided the increase for the coming year is at least 442—the increase of the past year—there will be, at the close of 1915, an overcrowding of 633, while any appropriations granted by the Legislature of 1915 will not be available until from one and one-half to two years later, when the overcrowding will be still greater. It is, therefore, necessary that appropriations for accommodations for 525 patients and 254 nurses planned for this year be granted."

"An increase of 274 this year in the number of feeble-minded being cared for is reported. The board says that immediate provision should be made for the feeble-minded because of the large number of this class of persons in the state.

"Three recommendations are made by the board: (1) To make the Foxboro State Hospital a receiving hospital for the insane, (2) to change the character of the Worcester State

Asylum to a receiving hospital, and to change its name to the Grafton State Hospital, and (3) to purchase land as an adjunct to the Northampton State Hospital so as to provide for the insane in western Massachusetts."

The report also recommends the following methods in treating mental deviates:—

"1. Examine all defective delinquents in all state institutions.

"2. Systematize the work so that the personal history, the mental state of every person confined and tendency to crime are recorded.

"3. Make every insane person useful during his detention.

"4. Increase the industrial work of every hospital with a view at some time to make all insane institutions in the state self-supporting.

"5. Make it possible to have more receiving hospitals. The only authorized receiving hospital at present is at Medfield. It is proposed to have Worcester and Foxboro also as receiving hospitals."

EXAMINATION OF CANDIDATES FOR ASSISTANT SURGEON.

UNITED STATES PUBLIC HEALTH SERVICE.

Boards of commissioned medical officers will be convened to meet at the Bureau of Public Health Service, 3 B Street, S.E., Washington, D. C., and at the Marine Hospitals of Boston, Mass.; New York, N. Y.; Chicago, Ill.; St. Louis, Mo.; Louisville, Ky.; New Orleans, La., and San Francisco, Cal., on Monday, March 8, 1915, at 10 A.M., for the purpose of examining candidates for admission to the grade of assistant surgeon in the Public Health Service, when applications for examination at these stations are received in the Bureau.

Candidates must be between 23 and 32 years of age, graduates of a reputable medical college, and must furnish testimonials from two responsible persons as to their professional and moral character. Service in hospitals for the insane or experience in the detection of mental diseases will be considered and credited in the examination. Candidates must have had one year's hospital experience or two years' professional work.

Assistant surgeons receive \$2000, passed assistant surgeons \$2400, surgeons \$3000, senior surgeons \$3500, and assistant surgeon generals \$4000 a year. When quarters are not provided, commutation at the rate of \$30, \$40, and \$50 a month, according to the grade, is allowed. All grades receive longevity pay, 10 per cent, in addition to the regular salary for every five years up to 40 per cent. after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. An invitation to appear before the board of examiners, address "Surgeon-General, Public Health Service, Washington, D. C."

BELGIAN PHYSICIANS' RELIEF FUND.

Report of the Treasurer of the Committee of American Physicians for the aid of the Belgian profession, for the week ending January 23, 1915.

Diplomatic arrangements have just been completed whereby drugs and instruments for civilian physicians may be sent into Belgium. Recent advices from Dr.

Herbert Spencer of London show that our Belgian colleagues are literally starving.

Three hundred additional boxes of food have been purchased at a cost of \$660.00.

Contributions:

Dr. W. A. Coventry, Duluth, Minn.....	\$ 10.00

NOTICES.

Physicians visiting the city will be cordially welcomed at the following clinics on the days and hours specified.

BOSTON CITY HOSPITAL.—After January 1, 1915, public operations will be performed in the Surgical Amphitheatre each week, on Thursdays, Fridays and Saturdays, at 10 o'clock.

Thursday: First Surgical Service. Dr. Blake
Friday. Third Surgical Service. Dr. Nichols, and
Fourth Surgical (G-U) Service, Dr. Thorndike.

Saturday: Second Surgical Service. Dr. Lund.
Notice of these operations will be sent to anyone expressing his desire to receive it.

CARNEY HOSPITAL.—Dr. Bottomley and Dr. Mahoney will hold an operative surgical clinic every Wednesday at 9 A.M., and at the same hour on the same day Dr. W. R. MacAusland will hold an orthopedic clinic. All physicians are welcome to attend.

MASSACHUSETTS GENERAL HOSPITAL.—1. A surgical clinic Friday, at 9 in the out-patient amphitheatre. 2. Operations in the Bigelow amphitheatre Saturdays from 10 to 1. 3. Operations in the Surgical Building except Sunday, from 9 to 1. 4. Daily surgical ward visits at which visiting physicians will be welcome. 5. Clinic in medicine, Monday and Thursday at 9, by Dr. D. L. Edsall. 6. Clinic in neurology, Tuesday at 9, by Dr. E. W. Taylor. 7. Clinic in medicine and pathology Tuesdays at 12, by Drs. R. C. and H. Cabot and O. Richardson. 8. Clinic in dermatology, Thursday at 9, by Dr. C. J. White.

PETER BENT BRIGHAM HOSPITAL.—Physicians visiting the city will always be cordially welcomed at the Peter Bent Brigham Hospital.

The medical visit takes place regularly every morning beginning at 10 o'clock.

Operations are usually going on throughout the forenoon in the surgical amphitheatre.

The surgical clinic is held in the clinical amphitheatre on Wednesdays at 12.30 P.M.

The medical clinic is held in the clinical amphitheatre on Mondays at 12.30 P.M.

The clinico-pathological demonstration is held in the clinical amphitheatre on Fridays at 3.30 P.M.

SOCIETY NOTICE.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—Owing to a change in the program of our meetings, the next meeting of the Middlesex South District will be held at the Massachusetts General Hospital, Out-Patient Amphitheatre, on Wednesday, Feb. 10, 1915, at 12 o'clock noon. Dr. Richard C. Cabot of Boston will speak on "Some Puzzling Cases Before and After Death."

LYMAN S. HAPGOOD, M.D., *Secretary*.

RECENT DEATHS.

DR. JAMES M. BODINE, who died on January 25, at Louisville, Ky., was born in 1830. He was for many years dean of the medical department of the University of Louisville.

DR. HARRY CLIFTON BOUTELLE, who died on January 24 of pneumonia at Danvers, Mass., was born in Fitchburg on June 21, 1875. He received the degree of M.D. from the Harvard Medical School in 1899, settled at first in the practise of his profession at Boston where he served for several years as a school physician, and removed to Danvers in 1902. He was a member of the American Medical Association, a Fellow of The Massachusetts Medical Society and a member of the Essex District Medical Society. He is survived by his widow and by one son. At the time of his death he was a Councillor of The Massachusetts Medical Society from the Essex South District.

DR. MAX HEYDE, a docent for surgery at the University of Marburg, Germany, has died of typhoid fever contracted while serving in a medical capacity with the German army.

DR. WILLIAM H. LANGDON, who died in Wayland, Mass., on January 26, was born in Brookline, Mass., in 1871. He graduated from Tufts Dental School in 1896 and since that time has practised his profession in Boston.

DR. HERBERT JAMES PRATT, who died at Plymouth, Mass., on January 21, was born in Medford, Mass., in 1842. He received the degree of A.B. from Harvard in 1863 and that of M.D. in 1868. He practised his profession for ten years in Minneapolis, Minn., and subsequently had devoted himself extensively to travel and study abroad. He was unmarried.

DR. BENJAMIN SHARP, who died on January 21 at Beaufort, N. C., was born in Germantown, Pa., on November 1, 1858. After studying at Swarthmore College, he received the degree of M.D. from the University of Pennsylvania and subsequently studied abroad in Bavaria, Berlin, Leipzig and Naples.

In 1883 Dr. Sharp became professor of invertebrate zoölogy at the Academy of Natural Sciences, Philadelphia, and two years later became professor of zoölogy at the University of Pennsylvania. He was a life member and corresponding secretary of the Academy of Natural Sciences, for which he made several expeditions, collecting in the Caribbean Islands in the winter of 1888-9, and in the Hawaiian Islands in the summer of 1893. He also made an expedition to Alaska and Siberia on the United States revenue cutter *Bear*. He was a member of the American Philosophical Society, Boston Society of Natural History, and was vice-president of the Nantucket Historical Association. Dr. Sharp served in the Massachusetts Legislature from 1910 to 1913 as representative from Nantucket. Dr. Sharp had been, at various times, a resident of Brookline and Nantucket, Mass. In 1901 he acted as zoölogist of Commander Peary's first Arctic expedition.

DR. SIR ROBERT SIMON, professor of therapeutics at the University of Birmingham, England, has died recently at the age of 84.

DR. CLINTON WAGNER, first professor of laryngology and rhinology in the New York Post-Graduate Hospital and Medical School, has recently died in Switzerland at the age of 74.

DR. LEVI FRANCIS WARNER, who died on January 20 in New York City was born at South Glastonbury, Conn., in 1864. He received the degree of A.B. from Williams College in 1885 and that of M.D. from the Columbia University Medical School in 1889. He was for eight years a member of the New York Board of Police Surgeons, physician-in-chief to the New York Dispensary and visiting physician to St. Francis Hospital. He was a member of the New York County Medical Society and of the St. Luke's Hospital Alumni Association.

BOOKS AND PAMPHLETS RECEIVED.

Text Book of Surgical Operations, by Prof. Fedor Krause, M.D. Translated and edited by Albert Ehrenfried, M.D. Vol. I. Rebman Company. New York. 1915.

Autogenous Serum in the Treatment of Psoriasis, by Howard Fox, M.D. Reprint.

Harvard University Catalogue. 1914-1915.

International Clinic Week at the New York Polytechnic Medical School and Hospital during the International Surgical Congress, April, 1914.

The Routine Administration of Ether in Measured Dosage, by Albert H. Miller, M.D.

Physical Examination of Workers, by J. W. Schereschewsky. Reprint No. 234. Public Health Report.

The Nervous System and Its Conservation, by Percy Goldthwait Stiles. W. B. Saunders Co.

Transactions of the American Surgical Society. Vol. 32.

Infection, Immunity and Specific Therapy, by John A. Kolmer, M.D. W. B. Saunders Co. 1915.

Dissection Methods and Guides, by David Gregg Nethany. W. B. Saunders Co. 1915.

Diagnostic and Therapeutic Technic, by Albert S. Morrow. W. B. Saunders Co. 1915.

A Laboratory Manual and Text-book of Embryology, by Charles W. Prentiss. W. B. Saunders Co. 1915.

VENEREAL DISEASE AND PROSTITUTION.*

BY WALTER D. BIBERBACH, M.D., WORCESTER, MASS.

IN 160 A.D. Galen recognized a disease affecting the urethral tract and named this disease "gonorrhea," which he believed was an involuntary escape of semen. Lacroix has stated that during the Middle Ages, Paris quartered its prostitutes in a quarter known as the clavier section, and it was from this locality that the term "clap" originated. So today we still have the words "clap" and "gonorrhea" which are used interchangeably by many physicians. From these two words there has developed a number of vulgar names which are used by the laity when referring to gonorrhea, such as "the morning drop," "nipper" and "a dose".

Although there are no means of positively identifying gonorrhea in the early ages, it is almost certain that the disease can be traced back to the earliest records of human life.

In 1530 Fracastor, an Italian physician, published a poem entitled, "Syphilis sive Morbus Gallicus." In this poem he describes the pagan gods and assumes that a shepherd, whom he terms Syphilus, had addressed offensive words to Apollo. The god in order to punish him struck him with a disease of the genital organs. The inhabitants of the country afterwards call this the Disease of Syphilus, or Syphilis. Opinions differ as to the source from which Fracastor

got the name, but the most probable origin according to Buret is *σύν* with and *φιλία* loving.

The date of origin is much debated, some dating it from 1494 when it was said to have been introduced into Europe from America by the crew who sailed with Christopher Columbus, in his search for a short route to the West Indies. This is disproved by the multitude of names given to it at the time of the great epidemic of the 15th century, for, had the disease been imported from America it probably would have been called "Mal Américain." Others claim that syphilis originated in Europe at the siege of Naples in 1493, but this cannot be proved, as it will be shown that no doubt the disease was present long before this time. The probable truth is that syphilis was universal, but not in the same degree in all countries or at all periods. It was also little understood. Syphilis is probably as old as man. The evidence in proof of this view we shall now proceed to consider.

It is impossible to fix a date as a limit to the prehistoric period, for at one and the same time we find certain nations cultivating science and writing treatises on medicine, while certain others were in a state of barbarity. At Solutre in the department of Saône-et-Loire is a prehistoric spot where human remains have been found, apparently of an Asiatic race. Here a woman's skeleton was discovered with nodes on the tibia, which were pronounced by Virehow and Parrot to be syphilitic. Parrot has found traces of congenital syphilitic bone disease in five skulls of Peruvian infants. This shows that syphilis existed in Peru before the Spanish Conquest. Jourdanet relates the history of syphilis in Mexico before the Conquest, and refers to the

* Read before the Worcester District Medical Society, Nov. 11, 1914.

opinion of Captain Cook that the disease existed in Oceania.

Syphilis existed among the Chinese five thousand years ago. In 1863 Dabry published a book on syphilis among the Chinese. He translated the manuscript which escaped the holocaust commanded by the Emperor Hoang-ty, who collected all the writings which existed. From these we learn through Dabry that the Chinese treated syphilis by mercurial inunctions, they also recognized scabies and treated it with sulphur. They understood venereal diseases better than they have been known since up to the time of Ricord. They knew the duality of chancres, which was only established in our time by Ricord; and also that syphilis and gonorrhea were distinct diseases. This quotation from Dabry's book is given by Buret, showing somewhat the extent of their knowledge: "It happens sometimes that, several months after the cure of a venereal sore the individual suffers suddenly from headache and fever, pains in the bones, and vertigo; a short time afterwards small copper-red spots appear on the face, which increase gradually. The face becomes bloated, chiefly the nose, the speech becomes difficult and there are pains and itching of the throat. The spots change to small purple nodules as large as peas which discharge a thick and foetid liquid; the body soon becomes covered with spots and nodules of the same nature; mucus flows from the nose and the breath is foul." There is also mention of condylomata, ulceration of the tonsils, and pigmentary syphilides of the neck. It is also stated that the disease may be transmitted to new-born infants. If we are astonished at this knowledge, we must remember that the Chinese invented gun powder when Europe was using the bow and arrow. Syphilis was apparently known to the Japanese but the records are very scanty.

Thus above, in a somewhat sketchy manner I have tried to show that gonorrhea and syphilis both have existed from the very earliest history of the human race. Passing along to the more enlightened ages we note that as civilization progressed so did the knowledge of gonorrhea and syphilis. After the Roman conquests the city of Rome, with its enormous population, settled down to a life of peace, luxury and vice, such as heretofore had been unknown in the world's history. As this time prostitution was rife. It was a common occurrence to see the nobles and men of power leave their palaces to spend the night in the brothels of the city. Some Romans even went so far as to maintain a brothel in their own palaces. If such form of vice was found among the wealthy there is no doubt but that similar conditions existed among the poor, but in a lower and more sordid scale. Rome provided for public baths which were used by men and women, boys and girls, who bathed in a state of nudity, and often these public baths were nothing more than houses of assignation. The shampooers and those who massaged the bathers

were members of the lowest class. Sometimes the interior of a private citizen's house had its walls decorated with lewd pictures and lascivious frescoes. There is little wonder that people at this time lead such lives when we find Nero, who was supposed to be their leader, a habitual frequenter of houses of prostitution and not only that, he dined in public with hordes of prostitutes. With such vice venereal disease must surely have thrived. The lives lead by the Greeks at this time were no better than that of the Romans and as a consequence venereal disease must have been prevalent among them to a large extent.

In the fifteenth chapter of Leviticus Moses warned the children of Israel of the dangers of a disease which was undoubtedly gonorrhea. He must have noted an alarming increase in its spread among his race, for in the Book of Leviticus he laid down definite sanitary and police regulations for its prevention. The historian Josephus relates how the Jews on their way to Canaan contracted venereal diseases, and as a result many of their own race were stricken with them. Thus gonorrhea and syphilis played an important rôle in the etiology of diseases of men and women in these ancient times.

The above must be true for at this time the Israelites were instructed to "put out of camp every leper, and every one that hath an issue." Probably many who were termed lepers were simply advanced cases of syphilis showing terrible tertiary lesions following faulty treatment. As for the interpretation of the word "issue," this is understood by many as referring to gonorrhea. However, some authorities believe that the term does not refer to a venereal disease.

Passing down through history we find that venereal disease was becoming so prevalent that the cause and treatment were given more consideration. In the fourteenth century the infectious nature of gonorrhea and the mode of its contagiousness were pretty definitely recognized. People became alarmed and ordered police regulations for its control, and medical supervision of houses of prostitution was inaugurated. In 1497 James IV issued a celebrated proclamation banishing all the infected from the City of Edinburgh. Henry VI placed police regulation in force, ordering all venereal patients from public hospitals, and required them to be strictly guarded at night. No wonder such stringent rules were taken, for in the fifteenth century all Europe was swept by an epidemic of syphilis, so severe that many lives were lost from this dreaded disease.

Up to this time you will note that very little was done to prevent the spread of gonorrhea or syphilis. When Rome was in her glory and prostitution flourished rife these diseases occupied very little space in medical literature. The Roman physician did not generally care to consider these diseases, believing that they were beneath his dignity. From what can be learned the Roman physicians refused to treat venereal

disease, and as a consequence the rich relied upon their slave doctors to care for them when suffering from either gonorrhea or syphilis. As for the poor it is hard to say what became of them.*

At the end of the fifteenth century and the beginning of the sixteenth century venereal disease had become such an important factor in the health of the public at large that the physicians began to study the cause and treatment more closely. Gonorrhea, especially in England, at that time became very prevalent and a large per cent. of prostitutes were infected. Both syphilis and gonorrhea, however, were somewhat confused, the physicians believing the latter disease a symptom of the former, and treated it as they did syphilis, generally with mercury. However, more rational views regarding the etiology of syphilis and gonorrhea were held by certain diagnosticians who carefully studied these diseases, and in 1554, P. Haschard wrote warnings against treating gonorrhea with mercury, stating that he believed the diseases were distinct and separate.

In 1750 the profession began to recognize that ophthalmia in the infant was associated with leucorrhea in the mother. From this it was shown that a mother suffering from gonorrhea at the time of giving birth to her child would transmit the infection from the vaginal tract to the infant's eyes. Discussions and differences of opinion as to the separate identity of these two diseases continued until the eighteenth century when it was generally recognized by all physicians that gonorrhea and syphilis were two different diseases. A little later, in 1767, this general agreement was again torn asunder, for Sir John Hunter offered himself as a sacrifice for the cause under dispute. He made two punctures in his penis with pus taken from a supposed case of gonorrhea. As a result he developed syphilis, having the secondary lesions such as mucous patches on the tonsils, together with a general glandular enlargement. As a result of Hunter's experiment came the conclusion that syphilis developed from gonorrhea. The medical profession here again changed their minds and went back to the old theory that gonorrhea and syphilis were the same disease, one developing from the other. This we would naturally expect, for Hunter was at this time one of the leading physicians and surgeons in Europe and his upright opinion carried great weight. It has been mentioned that probably the pus with which Hunter inoculated himself was taken from a patient suffering from a urethral chancre which was mistaken at that time for gonorrhea. Many investigators, however, did not stop with this report but continued the question by means of original research. Hale and Bell, from their work, taught that gonorrhea and syphilis were

different diseases. Bell showed by inoculating the urethra in two physicians that while they developed gonorrhea they did not contract syphilis. This experiment stimulated other investigators and in 1811 Hernandez inoculated seventeen convicts with gonorrheal pus, and all developed gonorrhea, not one contracting syphilis.

This experiment carried great weight with the profession in general but a new dispute now arose. Caron, Devergie and Desruelles taught that gonorrhea was not caused by any specific virus and the German believed that it was a general infection. Thus opinion was left in a much unsettled state. In 1837 Phillippe Ricord, a physician with a large experience, made 667 inoculations of gonorrheal pus in the urethras of different individuals and in not a single case did syphilis develop. These experiments of Ricord's and the brilliant manner in which he presented his findings definitely established the separate identity of gonorrhea and syphilis.

About this time there came on the scene another generation of men such as Koch, Pasteur and others who began to extend their scientific study to the laboratory in the hope of finding the cause of these diseases and ending this lengthy discussion. After much laboratory work by many investigators, Albert Neisser on July 12, 1879, described a micrococcus that he stated was the cause of gonorrhea. His conclusions were drawn from the study of thirty-five cases. The micrococcus was also demonstrated in seven cases of purulent ophthalmia. He later demonstrated these micrococci by employing Koch's method, thereby establishing without a doubt that gonorrhea was a separate disease and was caused by the gonococcus.

Later with advanced laboratory methods established by the Germans many investigators gave us our clear knowledge of gonorrhea and the pathological conditions produced by this disease. With the question of gonorrhea clearly settled in their minds the profession now determined to find the cause of syphilis, and in 1905 Schaudinn and Hoffmann discovered the spirocheta pallida, an organism found in secretions from syphilitic sores, that is now recognized as the cause of this dreaded disease.

Now that we have definitely settled the cause of both gonorrhea and syphilis let us consider the prevalence of these diseases. Neisser states that with the exception of measles, gonorrhea is the most wide-spread of all diseases. It is the greatest producer of involuntary "race suicide" and by sterilization and abortion does more to depopulate the country than does any other disease.

It is estimated that at the present time we have 500,000 prostitutes in this country and that 40,000 die annually. As nearly as can be estimated 30% of these deaths are caused by gonorrhea. In pelvic infection in women we find the cause is generally due to gonorrhea and different investigators claim that a majority of abdominal operations on women are performed

*The rich were treated by their slave doctors, while the poor were attended by the *archiatri*, who occupied about the same position as our district or city physician.

for conditions which originate from this dreaded disease. I will quote some of the figures given by different investigators claiming the percentage of pelvic infection caused by gonorrhea. Price claims 90%; Morris, whose figures were taken from dispensary patients, states 80%; Pozzi and Frederic 75%. Morrow and Bridgman have reported that in the State Training School for Girls at Geneva, Illinois, approximately 55% of the inmates have gonorrhea at the time of their entrance. Dröse, Saenger and Eberhard have shown that on examination of 1361 gynecologic patients 12.7% were infected with gonorrhea.

In carefully considering these figures we can safely say that gonorrhea causes 50% of all pelvic inflammatory diseases in women. Gonorrhea is the king of sterility and Neisser, Bumm and Fürbringer state that 30 to 50% of all childless marriages are directly caused by this disease. In France, it is claimed that out of 10,000,000 families, 2,000,000 are without issue. With these figures Neisser believes that in nearly 1,000,000 of these sterile marriages in France, gonorrhea is the etiologic factor.

In the United States census of 1900 for the blind and deaf, ophthalmia neonatorum was the cause of blindness in 25.02%. It is claimed that 10% of all blindness in the world may be blamed to gonorrhea.

In 1901 a committee was appointed to consider the prevention of venereal diseases in New York City, and circulars were sent to 4750 physicians inquiring as to venereal diseases. From the replies¹ received it was estimated that there were 200,000 active venereal cases walking in the streets of New York daily.

The Committee on Prophylaxis of Venereal Diseases of the Washington State Medical Association informs us that 80% of all men in large cities have had gonorrhea once or several times, 45% infect their wives, and 80% of all operations upon women for diseases of the uterus and adenexa are caused by this disease. With this report it is stated that 20% of blindness results from gonorrhea. Bierhoff estimates that in New York today there are at least 1,000,000 persons affected with venereal disease, and of this number 800,000 are suffering from gonorrhea. Morrow believed that there are 250,000 married women suffering from gonorrhea and that 1,500,000 men contract gonorrhea annually.

Hepburn reports that in Baltimore during 1906, 3090 cases of venereal diseases were treated by physicians in private practice and 6390 cases in dispensaries. During the same year in Baltimore there were treated 575 cases of measles, 1172 cases of diphtheria, 577 cases of scarlet fever, 175 cases of chicken-pox, 58 cases of small-pox, and 733 cases of tuberculosis, making a total of 3310 cases of infectious diseases against a total of 9450 cases of venereal disease.

¹ Report of the Committee of Seven, Med. New York, Dec. 21, 1909.

Swarts, in the report of the New York State Sanitary Officers, in 1910, states that 70% of all women who come to New York hospitals for treatment of venereal diseases are reputable married women who have been innocently infected by their husbands. He also reports 12,500 cases of measles, 11,500 cases of diphtheria, 19,000 cases of tuberculosis, making in round numbers 41,000 cases of infectious diseases. During this same period there were 243,000 cases of venereal diseases. In Germany, Litchfield estimates that in Berlin there are infected annually from four to five per cent. of the soldiers, 13 to 30% of waitresses, 16% of salesmen, and 52% of students. In a report of April, 1910, it was estimated that 100,000 persons were treated daily in Germany for venereal diseases.

These last figures I wish to mention to show that venereal disease is prevalent to a large extent all over the world and that the United States is not the only home of these dreaded diseases.

Generally most statistics taken from civil life are more or less inaccurate. In the army and navy conditions exist whereby frequent medical examinations are held. In this way statistics as to the prevalence of venereal diseases can be relied on with more certainty. It has been generally thought that in the army and navy venereal diseases are more frequent than in civil life. Von Topy states the relative venereal morbidity in armies bears a close relationship to the prevalence of this class of disease among civilians in the district in which the soldiers are quartered.

Munson gives the following figures relative to the prevalence of venereal disease per 1,000 in armies:—

Germany	29.9
Russia	36.0
Japan	40.0
Holland	48.0
France	49.0
Austria-Hungary	60.0
Great Britain (Home)	173.8
“ “ (Foreign)	522.3
United States	73.0

With this large per cent. of infection in the United States army it is easy to see how venereal diseases hold first place for admissions to hospitals and cause more discharges and render more men non-efficient than any other single factor. About the same can be said of the United States Navy. For a five years' period, from 1904 to 1909, according to Report of Surgeon General U. S. N., with an average of 43,165 men in the navy and marine corps, there were admitted to the hospitals for treatment for venereal diseases 32,852 patients, 11,526 were suffering from gonorrhea and 4890 from syphilis. The remainder were treated for other forms of genito-urinary diseases.

With this vast amount of venereal disease present there can be no question as to the existence of prostitution throughout the United States. It has been estimated that New York today has at least 75,000 prostitutes and other cities have the same number in proportion to their population. With such conditions present venereal disease costs the country a great deal of money. Kelley in *Jour. Amer. Med. Asso.*, October 6, 1912, estimated that America spent three billion dollars a year as a result of these diseases. The Chicago Vice Commission has estimated that profits obtained from prostitution in that city amount to at least \$15,000,000 annually.

Now that we are aware that the prevalence of venereal disease is so great the question of controlling such infection should receive the attention of every physician and student of sociology. The question of prevention of venereal disease is a subject that most medical men have not cared to discuss. Some are willing to reap whatever financial gain they may obtain for the treatment of these cases without the least care of how the public is protected from infection from this class of patients. This is more true of the English speaking nations, for statistics show how prevalent the disease is at the present time and how little is being done to check its wide spread menace to public and private health. Our boards of health still ignore venereal diseases, allowing syphilitics to wander about at large in the acute infectious stage of the disease, thus placing themselves in a position where they can infect the innocent.

A case which came under my care at the genito-urinary clinic at the Worcester City Hospital I may cite as an example.

A girl, twenty years of age, purchased a harmonica in a five and ten-cent store. The instrument lay on a counter and was exposed so that whoever wished was at liberty to pick it up and play on it. On returning to her home she practised on the instrument. On the second day she noticed that her lower lip was sore where there was an abrasion from a rough surface on the harmonica. The abrasion did not disappear under ordinary treatment, and at the end of two weeks it had become a sore of considerable size. She consulted a physician and was informed that she was suffering from "cold sore" and was advised to have it cauterized. Following cauterization the sore became enlarged to such an extent and associated with such marked glandular enlargement below the angles of both jaws that she consulted another physician who prescribed an ointment and gave her some medicine to take internally. During the sixth week from the time of the appearance of the sore on the lower lip patient noticed an eruption on her chest and abdomen. Not knowing the cause of this eruption she came to the hospital for a diagnosis and was referred to my clinic. On examination she presented a hard indurated sore on the lower lip which had partly healed leaving a hard area the size of one-quarter of a walnut. There was a general glandular enlargement, more marked under the angle of the jaw on the same side as the sore. On the back, arms, abdomen and thighs was

a diffused roseolate macular eruption. This associated with other signs and symptoms plus a positive Wassermann test proved the case to be syphilis.

In this case we have a girl of twenty suffering from a disease that she knew nothing of. Her infection was contracted in an innocent way. The most probable manner was that some person wandering about in the early infectious stage of syphilis had picked up the instrument and attempted to play it. His mouth contained mucous patches which were applied to the playing surface of the instrument infecting it with the spirocheta pallida which in turn was the cause of the chancre on the lip of the innocent patient. Up to the time of consulting me the patient knew nothing as to the highly infectious state she was in. She did not realize the possibility of infecting other members of the family, and in consequence no forms of prophylaxis were carried out.

In this case, if we had medical supervision established legally for the prevention of venereal diseases this patient would not have met with this infection. Here we see the lax condition of our boards of health, not due to their fault, but simply because there is no law to compel them to single out venereal disease and try to reduce its prevalence. To prevent such forms of infection I believe that there should be established a board in each city entirely separate from the local board of health but associated with either a national or state board, and that its work should be for the prevention of venereal diseases. When cases are discovered they should be reported to this board and if it is found that the patients' circumstances are such that they are unable to receive private attention, then a clinic should be provided for their care. The patients should be required to report regularly for treatment and for instructions, and on failing to do so should be reported immediately to this board which will in turn look them up and legally inform them that they are to abide by the instructions.

On the other hand, if the patient can afford private attention then his physician is held responsible for the control of his case, until he is in such condition as not to infect others. This class of patients should also be reported to the board as soon as a positive diagnosis of syphilis is made, and if they refuse to follow the physician's advice they should be reported and treated in a manner similar to the dispensary case.

There is no doubt that under the present conditions venereal diseases are alarmingly on the increase, and the question arises what methods shall be used to prevent their spread. First we must consider the source of infection and then apply suitable forms of prophylaxis. In the United States at the present time there are in round numbers at least 500,000 prostitutes, and of this number over 50% are infected with some form of venereal disease. On the other

hand there is a large number of males suffering from chronic infections who remain uncured either from ignorance or the lack of funds to receive proper treatment.

The fact that I believe that women are for many reasons the most prolific source of infection would lead me first to consider, how shall prostitution be controlled so as to reduce venereal infection to a smaller percentage. We realize that it is a sheer absurdity to believe that prostitution can ever be completely eradicated. It has existed from the very beginning of the human race and will surely continue. To try to directly control sexual indulgence would be useless and the time would be wasted, for the appetite forms one of the strongest, if not the strongest instincts of the human race. We must consider that if it were not for this passion the world would soon be depopulated. Probably no greater cause exists today in the producing of prostitution than the high cost of living. The increased cost of living postpones marriage and leaves in every city a large number of healthy individuals of both sexes whose normal sexual desires have no legitimate means of gratification. We must sorrowfully confess that the home environment of many girls is not the best, and if such is the case we must consider her welfare when away from home. Surely prostitution does not begin at home, nor does it begin suddenly. It is a gradual development and is contracted from our "social evils." The greatest evils in my mind are the cheap dance halls and places of entertainment associated with the paying of a "low living wage." If these economic and social factors were better regulated I believe that prostitution would not be so great.

Realizing that it is impossible absolutely to abolish prostitution, then we must consider what methods are the best to prevent the spread of venereal diseases by this source.

First, let us consider what other nations are doing. Germany has organized a department which consists of special police and medical men. The police department looks after the supervision of the prostitutes, seeing that they do not solicit in the streets. If they do, they are warned, and should they be caught a second time they are brought to the police station where they are given a talk and provided with a booklet containing information concerning places where medical treatment is given and describing the dangers of illicit intercourse, venereal disease, and the manner in which it is spread. If the girl is under age notice is sent to her parents. If, despite these warnings, she persists in her course of living she is examined, and if found to be diseased she is sent to a hospital where she is detained, and treated until the period of her infectiousness is over. If she is found to be free from infection she is inscribed on the records and given a book that is countersigned at each medical examination. No girl under eighteen years is inscribed, but should she be

infected she is sent to a hospital for treatment. The police in performing their duties wear plain clothes and if an arrest is made a closed cab is employed. The police records are available only to members of this board. The department occupies separate buildings having private entrances, exits, and waiting rooms for the women. The women are well treated and the entire procedure is carried out with as little publicity as possible.

Berlin, which is a city of 2,500,000 population, is divided into twelve districts, each of which has a physician in charge. The first examination is made by female physicians. No woman who shows that she is earning money elsewhere can be inscribed, and if at any time she should care to reform, her name is then removed from the inscribed list. This is about the general method employed in Germany; however the methods vary somewhat in different cities. In Dresden a rule is made whereby scrapings from the cervix and urethra are stained and cultures grown. The prostitutes are divided into three classes. Class I consists of women under the age of 24 years, and of all women who have not been under control for one year. Class II of women between 24 and 34 years of age. These are examined once a week. Class III, women over 35 years of age, are examined every two weeks. All women are given advice as to hygienic regulations and are advised against associating with minors. They are asked to dress decently and conduct themselves in a proper manner when in public. They cannot visit parks and are not allowed to show themselves at the windows of their dwellings. These are some of the rules and regulations that the prostitutes are compelled to carry out. As a result of this method of controlling prostitutes it is claimed that venereal infection has been considerably reduced. DeForest reported that in Dresden infection had been reduced 40% among the women. Biernoff states that in 1911, 3024 sources of infection were removed by the above method. Infection is somewhat uncommon in the registered prostitutes and good order is maintained throughout the larger cities of Germany.

In Norway venereal diseases are reported and patients are treated at the public expense. Treatment is compulsory and physicians are obliged to inform the patient as to the infectious character of the disease. Should the patient infect another then he or she is liable for the expense or treatment and damage suffered by the one infected. Physicians are in charge of the sanitary offices and report good work.

In France prostitutes are under police and medical control. If a woman in the street is suspected of prostitution she is arrested by special police detached for this work. If it is proven that she is a prostitute she is inscribed and given a card which is countersigned at each examination. Inmates of houses are examined weekly and others are obliged to report for examination every two weeks. At any time they

are found to be diseased they are sent to a special hospital where they are detained until they are free from danger of infecting others. Paris has over 100,000 prostitutes and it has been estimated by Fournier that only 7.08% of infection appearing in men is contracted from public prostitutes.

In England attempts at police regulation have been tried and the results have been a failure so that this system is now abandoned.

In Italy, free beds are provided for venereal patients who are treated until all danger of infecting others is passed. Japan, Austro-Hungary and Havana also carry out a similar system.

In the United States the method of dealing with prostitution varies in different localities, this being due to different laws in each state. The general feeling has been strongly against any form of official recognition. However, some cities have made an attempt to regulate prostitution. Detroit at one time contained 125 houses of ill fame and registered about 500 prostitutes. This soon became unpopular and at the end of one year was abandoned.

In New York in the year 1910 the Page Bill was passed which provided for medical examination of all females convicted of soliciting. The examination was made by a female physician, and if a person of this class was found to be affected she was sent to a public hospital having a ward for the treatment of the disease from which she was suffering. After being cured so as not to infect others she was discharged and released from custody upon the written order of the officer in charge of the institution to which she was committed. If the prisoner was cured prior to the expiration of her sentence she was then transferred to a work-house and discharged at the end of her time. On discharge no certificate of any kind was given to the woman. From reports of the Board of Police Magistrates the law was effecting some good. After having been in effect for about one year the Page Law was declared unconstitutional, and all examinations were suspended.

In Salt Lake City prostitution is ignored but officials give a license under the name of a bond. Every month the prostitutes are arrested and then bonded for \$10.00 or \$15.00 a head to appear and answer to the charge of vagrancy. They never appear and the bond is forfeited, the money going to the city treasury. This acts as a license to the prostitute. This or similar methods have been carried out in the different cities throughout the United States.

I understand that in Portsmouth, N. H., the city officials recognize that with the large number of soldiers stationed in that city vice and venereal disease are bound to spread. They have given permission to houses in certain locations for the keeping of prostitutes which are said to number about one hundred. The women are restricted and are not allowed in public but only when on business and then they must go un-

corted. They are examined once a week by a physician who reports their condition to the chief of police. When a new arrival comes to the city she reports to the police, who take her record and give instructions as to her mode of living. Should she at any time fail to obey these instructions she is ordered from the city or arrested. At certain times a moral wave sweeps the city and the police officials order all houses of ill fame closed until this condition subsides, when they again give their consent and protection.

In the early part of my paper I have mentioned that probably 50% or more of the prostitutes in the United States are infected with some form of venereal disease. From cases that come to me for treatment I would judge 80 to 90% receive their infection from public prostitutes. There is no wonder that this condition exists when we consider that at the present time we have no methods of controlling these classes of patients who wander about in a highly infectious state.

Our methods of controlling prostitution in the United States at the present time do nothing but open up illegal avenues for "graft," whereby certain officials add to their salaries at the city's expense and to the detriment of the public health.

Would it not be better to regulate prostitution if by so doing we could eliminate houses of ill repute that thrive along our country roads, rid the police systems of many grafts, wipe out the white slave traffic and the harboring of inmates, drive away the clandestine prostitutes and dive keeper, and lastly, an important point, stop the sale of liquor in brothels which in many cases is the cause of prostitution?

The results obtained by the Germans, I believe, show that by controlling prostitution they have been able to check the spread of venereal disease.

In Paris, a city of 100,000 prostitutes, Fournier shows that only 7.08% of the infected cases are contracted from public prostitutes. If prostitutes are under control I believe that it gives us a starting point whereby we will be able to reduce the number of these people to a smaller percentage. It will bring the prostitute before us in her early career, and the chances of reforming her are greater than in later life. The regulation of prostitution if properly enforced controls only the females, the male being free to spread the disease, therefore it is proper to consider the control of infection through this means. There is no doubt that a large proportion of patients suffering from venereal diseases are unable to seek the services of a private physician, and, as a consequence, are obliged to roam about in an infectious state. Throughout our cities the dispensaries and hospitals provide in a very scanty way for the care of such patients. This is more true in smaller cities where no medical schools are established. In larger cities, however, where medical schools are found, there are

one or more dispensaries associated with a general hospital where attention is given to patients suffering from venereal diseases. These are not established for the protection of the public but for the benefit of the medical student.

Cities with a population up to 100,000 inhabitants pay little attention to the treatment of venereal diseases. Should we compare the amount of infection present in cities of this size with large ones, where medical colleges are found, I believe that the percentage is as high in proportion to the population as it is in larger cities. I believe that every city or town of sufficient size that is provided with a hospital should see that there is a well-equipped department established for the care of venereal cases. This department should care for patients that are unable to pay for private attention elsewhere. The hospital should be equipped with a venereal ward and laboratory facilities for diagnosis and blood tests in order to determine the condition of patients. In conjunction with the ward it would be wise to have a special operating room for the giving of salvarsan and caring for such patients when surgical operating is advised. By doing so, patients in a highly infectious state will not come in contact with the surgical cases in the hospital. The city should furnish salvarsan free for the treatment of all cases that apply at the hospital and are unable to pay for the drug. Why not? A syphilitic patient who is in an infectious state is a danger to the community at large. He or she may be the means of infecting the innocent through drinking cups or many other means where the public is exposed.

We give out serum for the treatment of diphtheria and meningitis because we believe that persons infected with these diseases are dangerous to the public at large. We even go so far as to deprive them of their liberty by quarantine until they are not dangerous to the public. These diseases are curable and produce no after effects in the following generations. Yet for such a disease as syphilis that ruins homes, produces destruction and fills insane hospitals, we do not provide prophylaxis or care, still knowing that today it marks one of the greatest, if not the greatest danger to the race. If such is the condition why should not salvarsan be furnished by the state or city to be used in cases that are dangerous to the public? Is there any reason why we should not have the power of depriving of their liberty the highly infected cases that do not submit to proper treatment by placing them in quarantine until all danger to the public is past? My answer to this question would be that we should have the power just as we have in quarantining diphtheria, scarlet fever, and other infectious diseases. This can easily be accomplished if a venereal ward is established in our cities, and if a law is passed whereby physicians are obliged to report all cases of syphilis. In this way, cases that cannot provide for private attention outside will be cared for in one venereal ward. These patients are to be quarantined

until all danger of infecting others has passed. To do this will require very little time. Under proper treatment syphilitic patients who are highly infectious can be placed under control inside of two weeks.

Having the patient placed under control and where he is not dangerous to the public, we must provide some means of completing the cure. This can be carried out in our dispensaries which are associated with our hospitals. At the present time most hospitals are well-equipped to care for ambulatory cases, and the only thing required of the patient is to carry out the instructions that are given him. Venereal diseases when properly treated very seldom keep the patient from his work. To seek treatment at dispensary hours will eventually cost the patient his position. For this reason many cases remain away from treatment. These are the cases we wish to reach if we hope to produce a cure and protect the future generation. For this reason I believe that dispensaries in large cities should arrange their hours so that the working class can apply for treatment during the noon hour which is allowed them for lunch. Of course, where there is a large clinic one will not be able to treat all cases during the noon hour, and in such a condition, I believe that the establishment of an evening clinic is the proper solution.

By carrying out these methods patients will be encouraged and shown that everything is being done to cure them of their infection, and as a result we will be able to reach the chronic infected cases that are a danger to the community at large. By such curative and preventative efforts we not only will be safeguarding the community from the infective patient, but in the case of syphilis we will be insuring the individual's future against the distressing tertiary stages and the incapacitating parasyphilitic forms, at the same time conserving the progeny. The gonorrheic will be saved many distressing complications and much surgery. Sterility and blindness will be diminished, giving back to the community in vital force a value infinitely in excess of the cost.

DIFFERENTIAL DIAGNOSIS AND INDICATIONS FOR TREATMENT OF TUMORS OF THE NECK.

By OLIVER C. SMITH, M.D., HARTFORD, CONN.

Surgeon to Hartford Hospital.

RICHLY supplied with lymphatic and secretory glands, and exceedingly vascular, no region of the human body is more subject to inflammatory involvements and growths than the neck, unless it is the abdomen. The pathology of these lesions has a wide range, and their diagnosis is at

times difficult or impossible without the aid of sections and the microscope. Their correct diagnosis is extremely important, in order that appropriate treatment may be applied without loss of time, and that a correct prognosis may be made. In this discussion the word tumor is used in its broad sense as including all swellings, acute and chronic, as well as true neoplasms. The lesions of this area may be classified as follows:—

TUMORS OF THE NECK.

A. Inflammatory.

a. Acute:

1. Parotitis (mumps).
2. Submaxillary adenitis.
3. Cervical lymph adenitis.
4. Furunculosis and carbuncle.
5. Anthrax (malignant pustule).
6. Actinomyces.
7. Echinococcus cyst.

b. Chronic:

8. Chronic lymph adenitis.
9. Tuberculosis.
10. Syphilis.
11. Hodgkin's disease.
12. Mikulicz's disease.

B. Embryologic Malformations.

13. Branchial cysts.
14. Tumor of thyroglossal duct.

C. Neoplastic.

a. Benign:

15. Lipoma.
16. Fibroma.
17. Chondroma.
18. Osteoma.
19. Sebaceous cyst (wen).
20. Angioma.
 - a. Hemangioma.
 - b. Lymphangioma or hydrocele.
21. Hygroma.
22. Teratoma.
 - a. Dermoid cysts.
 - b. Mixed tumors of salivary glands.

b. Malignant:

23. Carcinoma and epithelioma.
24. Sarcoma.
25. Lymphosarcoma.

D. Tumors of Special Organs.

a. Thyroid.

26. Physiologic hypertrophy of menstruation and pregnancy.
27. Colloid adenoma (goitre) with or without cysts.
28. Parenchymatous hyperplasia.
29. Foetal adenoma.
30. Malignant disease.
 - a. Carcinoma.
 - b. Sarcoma.
- b. Carotid body (31).
- c. Aneurysm of aorta and carotids (32).
- d. Tumors of larynx (33).

INFLAMMATORY LESIONS.

Acute. Under this heading we have acute parotitis, and acute lymphadenitis of the submaxillary, cervical, sublingual and submental glands. Acute infections of these glands are due to pathogenic organisms, with the exception of a specific infection of the parotid gland, causing mumps and the occlusion swellings of the parotid or salivary ducts, which are caused by pressure or calculi with secondary infections developing.

Parotitis. The specific or infectious involvement of parotitis or mumps is accompanied by constitutional symptoms with sometimes a high range of temperature; the gland is swollen, tender and painful. Complications are unusual in a child, but in the adult male orchitis is a frequent accompaniment, and in a female congestion of the breasts, ovaries and labia is not uncommon.

The most frequent mistake in diagnosis is the confusion of mumps with cervical lymphadenitis; the latter occurs back of the jaw and below the ear, while in mumps the swelling extends forward upon the face and posterior to the sterno-mastoid muscle, the lobe of the ear being the center of the swelling. The parotids contain lymphatic glands in their substance. Infections may be carried into the parotid through these channels or by the blood stream. This form of parotitis is more frequently the result of metastasis or general infection than from a direct source. It occurs in typhoid and scarlet fever, the other infectious diseases and in suppurative lesions, both before and after operation. This form of parotitis should not be diagnosed as specific parotitis or mumps, as the condition requires early incision and drainage for relief of tension.

Acute lymphadenitis.

Submaxillary and Cervical Lymphadenitis. Acute infection and swelling of the submaxillary and cervical glands is not usually suppurative, and in an individual with good resistance the swelling frequently subsides under antiphlogistic treatment and with appropriate treatment of the throat, nose, teeth and mouth. The original focus should be carefully searched for and treated.

Acute suppurative lesions in the neck are most frequently found in the submaxillary region: the space above the carotid packet is the next most frequently involved. The intracapsular abscess of the salivary glands may become rapidly serious, due to tension under which the infec-

tion is held. Evidences of marked constitutional infection rapidly develop, extensive swelling occurs, causing respiratory disturbance, and occasionally death may result before active suppuration exists. This condition is known as Ludwig's angina. The acuteness of the onset and the marked local condition and constitutional symptoms leave little room for error in diagnosis of these cases. The treatment: early and thorough drainage by careful dissecting is advised, as the pus frequently lies in the region of the great vessels, and even the ordinarily safe method of Hilton may not be suitable in this deep area of the neck.

Furunculosis and Carbuncle. The neck is particularly liable to staphylococcic furuncles and carbuncles, the posterior area of the neck being the most frequently affected. The former frequently appear in series, and their diagnosis can hardly be mistaken. Incision, drainage, hot applications and the employment of autogenous vaccines are indicated in the former, and complete excision of the latter, the carbuncle, is the most desirable method of treatment where it can be carried out. The frequent association of glycosuria with carbuncle must be remembered and appropriate internal treatment employed.

Anthrax. Anthrax or malignant pustule is a rare infection on this continent; it may occur upon the neck, but is most frequently found upon the face and hands. An elevated pustule of varying dimensions with a depressed central scab is the early characteristic appearance. Removing this incrustation liberates a brownish, bloody fluid. The surrounding tissues become highly involved, and later purplish and gangrenous in appearance, although there may be no indication of suppuration. The occupation of the patient is important, diagnostically, as anthrax is known among other derivations as wool-sorters' disease. The finding of the anthrax bacillus is the laboratory diagnostic method of the greatest importance.

Actinomyces. This specific and infectious lesion, essentially a disease of the lower animals, and known as lumpy jaw in cattle, was first discovered in man by Israel¹ in 1878, the infecting agent being the ray fungus. The region of the face and neck are most frequently involved; it is an accident of young life, occurring more frequently in males. The disease is believed to be increasing in this country.

The portal of entrance to the region which interests us is usually an abrasion or ulceration about the tongue, teeth or cheeks. A hard, nodular, circumscribed swelling slowly appears in the subclavicular region or at the angle of the jaw. The skin becomes purplish and tends to break down. Secondary infection usually intervenes. The lesion progresses so slowly that the diagnosis may easily be confused with sarcoma or carcinoma, tuberculosis or syphilis. Characteristic granules are visible to the naked eye in the pus of actinomycotic lesions, and the ray fungus may be demonstrated under the

microscope. Its correct diagnosis is highly important, as vigorous and persistent treatment is essential. Liberation and destruction of the invading fungi by incision, curettage, silver nitrate applications locally, iodide of potassium internally, and the best of hygiene are the accepted methods of treatment.

Echinococcus Cysts. Echinococcus cysts fortunately rarely occur in the neck; they spring from the deep recesses and gradually bulge outward at the side of the neck, either anteriorly or posteriorly, to the sterno-mastoid muscle. As in many cystic tumors the aspirating needle is the surest method of diagnosis. The clear contents, containing the characteristic hooklets, is pathognomonic, and excision is the only treatment.

Chronic Lymph Adenitis. The continuation of an acute infection by the less virulent organisms of the salivary and cervical lymphatic glands may lead to chronic hyperplastic changes which slowly subside after the focus of infection is cured. A chronic indolent infection of the lymphatics and cellular tissues of the neck, causing dense induration, suppurating slowly and irregularly, first described by Reclus² in 1894, is known as Ligneous Phlegmon. No one specific organism is believed to cause this condition, all manner of organisms being found. The disease must be differentiated from syphilis, tuberculous adenitis and malignancy. The ordinary measures used for hastening suppuration are ineffectual. Small multiple abscesses or eventually a large abscess may develop, requiring incision and drainage.

Tuberculous cervical adenitis.

Tuberculosis. Tuberculosis is by far the most common cause of chronic glandular enlargement of the neck. The tubercular organisms in cases

of primary infection usually gain entrance by the tonsil, pharynx, nares, gums and teeth. The extension is through the lymph channels, the lymphatic glands harboring the bacilli, hyperplasia resulting, followed by softening and glandular destruction and caseation. These swellings vary in size from small nodules to extensive, deforming masses. Exacerbations and remissions are common. During the period of remission the patient and family are led to hope that the condition is recovering; later fresh invasion through one of the paths above indicated results in increase in the size of the growths, with involvement of additional glands. Most of the older writers discuss this condition as scrofula; it was considered to be the local expression of a general glandular disease. A more minute study of the lymphatic system by Poirier,³ Cuneo and others has taught us that the cervical lymphatic glands do not drain the thorax and the mediastinum, and we may conclude that cervical tuberculous adenitis remains a local condition until a hematogenous infection occurs.

The diagnosis of this condition is exceedingly important, as is the institution of prompt and thorough treatment. It is possible to confuse tuberculous adenitis with the more acute infections, also with Hodgkin's Disease, lymphosarcoma, lymphatic leukemia, syphilis and malignant neoplasms. Their chronicity and their association with evident lesions of the throat, nares or buccal cavity, the recessions and exacerbations, the absence of enlarged glands in other parts of the body, the fact of their occurring in children and young life, the absence of other general infections, such as syphilis, which can be determined by laboratory methods, all point to a diagnosis of tuberculous adenitis. It is, however, at times necessary to secure a section or to make an incision through the capsule of one of the glands to determine its true character.

The fact that there is at present a considerable diversity of opinion as to the proper treatment of cervical tuberculous adenitis, and that its occurrence is so exceedingly common, makes this one of the most important divisions of our subject. Groups of cases call for different lines of treatment: first, those with gross lesions as tonsillitis and adenitis with comparatively early invasion of the cervical glands. Our effort in these cases should be to clear the throat and nares of the disease-predisposing tissue. The tonsils and adenoids, the teeth and gums should also claim careful attention. Following these procedures the child or the young individual should be placed upon an anti-tuberculous régime with all that that implies. The application of iodine and other counter-irritants to the skin seems to be of little value. Many of the earlier cases in individuals of good resistance will recover with nothing further.

The second group includes cases where the local process has extended to decided enlargement and softening of the involved glands; it is this group that the surgeon sees most commonly.

The treatment indicated in the first group applies in these cases, and in addition, an incision for the removal of the involved mass, if feasible, cleaning out pus and caseous material, and an application to the invaded tissue of iodine, followed by alcohol, or very hot water. There should be slight provision for drainage at the inferior angle of the incision. In addition subsequent treatment by tuberculin or x-ray is of great value in many cases.

The third group presents a wide extension of the involved glands which have not gone on to suppuration. In these cases, if early improvement does not follow, the treatment applied to group one, with the possible addition of tuberculin or x-rays, and radical dissection of all the involved groups, should be employed. While the operation is extensive, in experienced and careful hands it is fairly safe, because there is an open dissection with all of the structures to be removed and to be avoided visible to the operator.

In the writer's experience there have occurred 78 operations for tuberculous cervical adenitis; there have been no fatalities nor any injuries of important structures. Up to 1910 at the Mayo clinic 649 patients were subjected to complete excision, and there were no immediate fatalities. Pulmonary tuberculosis, if not too extensive, is not a positive contra-indication. With selected methods of anesthesia, and the avoidance of ether, the pulmonary lesion should not be aggravated. The chief objection that the surgeon finds to operations upon these glands is the anticipated scar. This should be avoided as far as possible by making incisions in the normal creases of the neck, by careful suturing of the muscles and subcutaneous tissue, by the avoidance of coarse skin sutures, attention to accurate approximation, and the scrupulous avoidance of infection. It must be remembered that the scar of an incision may be much less extensive and unsightly than the wide and contracted scars of multiple sinuses. Tuberculous adenitis calls for careful judgment and good management. It is a mistake to recommend radical dissection in every case, and it is likewise a mistake to treat in an incomplete manner cases which tend to progress and resist all milder methods.

Syphilis. Chancre upon the lips and tongue is of common occurrence. The cervical glands become rapidly involved, or the chancre may have healed and the patient come complaining only of the glandular enlargement. The history of the chancre may be obscure and the diagnosis in doubt, or the chancre may be still in existence and may be confused with epithelioma. If the sore is in evidence it will have an indurated, reddish base and an ulcerated apex, which on pressure may bleed, but yields no whitish plugs as does the epithelioma. Examination of the scrapings of the ulcer on a dark field stage, in addition to the Wassermann test, should precede operations upon the lip and tongue where there is a possibility of the disease being syphilis. The

cervical glands in syphilis are not operable, but yield to general treatment, while in epithelioma they should always be thoroughly removed.

Hodgkin's Disease. Hodgkin's disease, known also as pseudo-leukemia and malignant lymphoma, is a serious constitutional disease with the early local manifestation of enlargement of the cervical glands. The glandular enlargement, unilateral at first, later becomes bilateral; other glands subsequently become involved, such as the supra-clavicular and axillary chains. Early writers considered this condition tubercular, but recent text-books state that all attempts to establish a bacterial organism as an etiologic factor in the disease have been unsuccessful. In 1910, however, Frankel⁴ and Much, three years later Negri⁵ and Mierniet abroad, Bunting⁶ and Yates, and Billings⁷ and Rosenow in this country, published observations which make it seem probable that a bacterial infection may be accountable for this strange disease. Bunting and Yates have reproduced this disease by inoculating monkeys with a culture obtained from the diseased glands. Billings and Rosenow have published a number of clinical cases; quite a few have improved, and one is apparently cured. The cervical glands enlarge rather rapidly, the submaxillaries being first involved; they are soft, painless, and generally precede any constitutional disturbance. Later there follows general bodily deterioration with cardiac weakness, edema, albuminuria and fatal termination in three to five years.

Hodgkin's disease must be differentiated from the more definite neoplasms; namely, sarcoma, carcinoma, and lympho-sarcoma; also from lymphatic leukemia and tuberculosis. Sarcoma of the lymph glands springs from the connective tissue of the glands and not from the lymphoid cells. They infiltrate widely and are hard and immovable; their course is much more rapid than that of Hodgkin's disease. Carcinoma of this region is usually superficial, commencing in the skin, or is secondary to carcinoma elsewhere. The involvement is hard, nodular, infiltrating, and rapid in its progress.

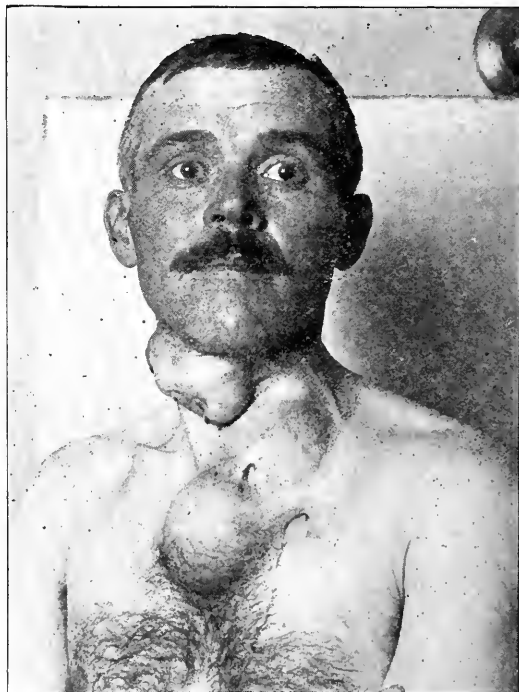

Branchiogenic carcinoma occurs in older individuals, usually females; they are deeply adherent and accompanied by pain. Lympho-sarcoma attacks one gland, usually in the upper part of the neck, breaks through the capsule and infiltrates the surrounding tissue. The skin early becomes discolored,—dark blue. Metastases occur in other organs but not to other groups of glands. Lymphatic leukemia is characterized by marked blood changes, chiefly a great increase in lymphocytes and a general lymphatic involvement. Prior to the use of Roentgen rays, and more recently the bacteriological efforts in treatment of Hodgkin's disease, arsenic was the main reliance, but the disease was almost invariably fatal. With these recent aids it may be proper now to remove the enlarged glands early. We have done this in one case with a satisfactory result thus far.

Mikulicz's Disease. A rather rare type of chronic inflammatory disease of the lachrymal and salivary glands was described in 1892 by Mikulicz,⁸ and the condition bears his name. The author has had no personal experience with this disease. A small percentage of these cases are associated with leukemia and enlargement of the spleen.

Wilder Tileston⁹ states that the cases to which the term Mikulicz's disease should be applied present the following features: chronic, painless; symmetrical enlargement of the salivary or lachrymal glands, or both, with or without enlargement of the spleen or lymph nodes. The disease runs a benign course with no tendency to recurrence after complete extirpation of the affected glands. A frequent cure is obtained under the use of arsenic, iodides or the x-ray and sometimes spontaneously. The case is supposed to be some infectious agent or a number of agencies. Tuberculosis, Hodgkin's disease and syphilis must be carefully excluded.

EMBRYOLOGIC MALFORMATIONS.

Branchial Cysts. The failure of one of the gill-clefts to close in the embryologic period results in a sinus in the neck or thorax, the inner opening of which is in the pharynx in the region

Branchiogenic cyst.

of Rosenmüller's fossa or one of the tonsils. There may or may not be an outer opening; if one is present it usually occurs anterior to the sterno-mastoid muscle and inferior to the hyoid bone. The sinus, however, may be found in the median line. It is generally recognized now that the sinus originates from the second cleft.

If the sinus is imperforate a cyst results. These cysts may vary much in size and may be uni- or multilocular. After a long period of the existence of sinus or cyst, or both, the skin may break down and the cyst discharge. Minute examination will find the cystic tract extending upward through the platysma muscle and deep fascia of the neck to the great cornua of the hyoid bone, thence on between the carotids, reaching the pharynx at the point before mentioned.

The diagnosis of these cysts may be confused with the cystic hygroma, with abscess, lymphangioma, the cysts of aberrant thyroids, tuberculous glands, and possibly lipoma and wens. The contents of these cysts varies from fatty, atheromatous material containing cholesterol crystals with absence of bacteria in non-infected cases, to that of a mucoid, gray, starchy material, the variation depending upon the character of the epithelial cells lining the cyst. If necessary, a portion of the cyst wall can be excised for examination. These cysts are frequently incised in the belief that they are abscesses. The only benefit of such an incision is to relieve tension. The proper operation is one of careful dissection.

Thyroglossal Cysts. Thyroglossal cysts result from incomplete obliteration of the thyroglossal duct, which extends from the foramen cecum to the isthmus of the thyroid. Like the branchiogenic cysts, they usually develop in young or middle life and occur at the base of the tongue or the floor of the mouth, or the cyst may appear in the midline, protruding above or below the hyoid bone. They may be confused with ranulas, dermoid cysts, and lipomata, and unless secondarily infected the contents are a gray, starchy mucus. The ranula is a translucent cyst filled with mucus and occurring at the base of the tongue. Dermoid cysts may occur in this location, but their contents establishes a diagnosis. The surgical treatment consists in carefully following up the duct to its origin. If a delicate probe cannot be passed through the duct, injection of methylene blue will aid in tracing its source. Failure to accomplish this generally results in recurrence.

NEOPLASTIC GROWTHS.

Benign. Lipoma occurs not infrequently in the neck, especially on the posterior surface. It is of slow growth and characteristic consistency, non-inflammatory, not painful, and regular in outline. Lipomata are not likely to be mistaken for other neoplasms; they are occasionally incorrectly diagnosed as wens and tuberculous glands; they rarely ever tend to malignancy; removal by incision is the only treatment.

Fibroma. These growths are not common in the neck; they originate in the deep fascia; they are painless, smooth, mobile, and yet their pathology must remain in doubt until they are excised, which is the only treatment.

Chondroma. True chondromas, aside from

the mixed tumors of the salivary glands, are extremely rare in the neck. They are benign, of slow growth, and of characteristically cartilaginous feel. A true chondroma of the hyoid bone is illustrated in Hertzler's¹⁰ work on tumors from a case of J. W. Perkins'. Operative removal is the only treatment.

Wens or Sebaceous Cysts are of common occurrence in all parts of the neck; their superficial relations and rounded form identify them in their primary state, but when broken down and infected with liquid contents and inflamed surface the diagnosis is not always simple. They have been opened with the anticipation of finding an abscess and have been mistaken for tuberculous glands. The treatment is removal by dissection of the cyst wall; incision and drainage practically always being followed by recurrence.

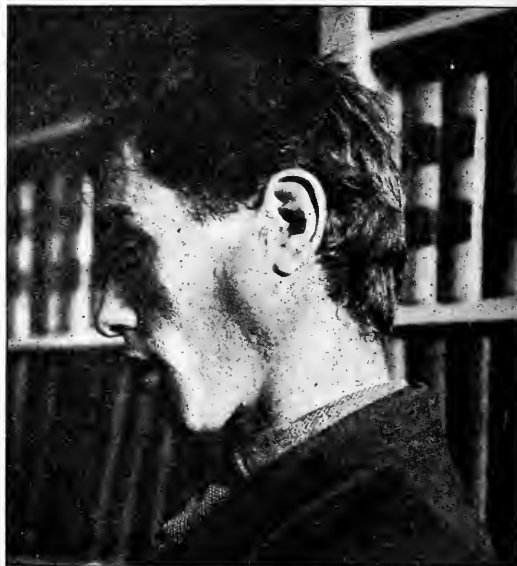

Angioma. Angiomata are divided into hemangioma and lymphangioma, and the hemangioma into superficial and cavernous. The neck and face furnish a common location for the superficial angioma. They can be scarcely confused with any other growth. The red, purplish color, slightly elevated surface, and the gradual extension, if occurring in a child, establish their identity. The cavernous angioma, occurring more frequently in the back of the neck, has thin, vascular walls, with little or no musculature. They may be superficial or deep, and are sometimes confused with sarcoma. The simple angioma may be removed by electrolysis, radium or operation, if the surface is not too extensive, while the cavernous variety requires a careful and quick dissection or deep ligation.

Lymphangioma. Lymphangiomata are like the foregoing with less tendency for new growth of vessels; they also may be superficial or deep, and occur more frequently in the neck than elsewhere. They are sometimes designated as hydrocele of the neck, varying in size, increasing or remaining stationary, rising above the clavicle, but demonstrably springing from below. The diagnosis can only be confused with other cysts, and their contents of lymph tell the true story. Fortunately they are rather rare, for their treatment is unsatisfactory. They occasionally subside spontaneously. Operation may be difficult or impossible. Puneture and injection of iodine in inoperable cases is recommended.

Hygroma. Hygromatous cysts occur most frequently in the neck and axilla; they are probably the result of embryonic sequestration of lymphatic tissue and retain the power of persistent, regular growth. They are usually discovered at or shortly after birth, but may not reach a size sufficient to have them brought to the attention of the physician until some months or years later. The writer has recently reported two cases with operation, to which communication Dr. A. M. Rowley added one case. These cysts are thin-walled, contain clear fluid, and may be easily mistaken for branchiogenic cysts or broken down glands, as they grow to a large

Hygroma cysticum colli.

Mixed tumor of the parotid gland.

size, and in some cases are most disfiguring and do not respond to treatment. Their early recognition and careful dissection is important.

Teratoma. These tumors are divided into dermoid cysts and mixed tumors of the salivary glands. The dermoid cysts are not uncommon in the neck, occurring along the lines of the branchial fissures. There are two varieties, sequestration and tubal dermoids. The former is much more common and is caused by an inclusion of the skin at the region of the embryonic fissures. The tubal dermoids occur in obsolete canals; hence their name. These cysts may be taken for sebaceous cysts or lipomata; the diagnosis is established by aspiration. The contents vary with the character of the tissue included. Soft sebaceous material predominates. Dermoids of other locations with more complicated inclusions furnish various products of epidermal cells. Their treatment is excision.

Mixed Tumors of the Salivary Glands. Mixed tumors of the salivary glands occur most frequently in the parotid. The author has observed six cases, four of which were operated upon; all were of the parotid gland. Of 56 cases operated upon at the Mayo clinic 50 were of the parotid and 6 of the submaxillary glands. F. C. Wood¹¹ published a series of 42 cases in 1904, and Wilson¹² and Willis reporting from the Mayo clinic have given a tabulated series of 56 operative cases. From these 110 cases, which have been most carefully studied, conclusions can be drawn as to age, sex incidence, clinical course and tendency to recurrence. They occur somewhat more frequently in males, and during each decade from the first to the seventh, 66% during the first four decades.

There is a large amount of literature upon the subject, and there has been much discussion as to the etiology of these tumors. Wilson and Willis concluded that they are mesenchymata of

embryonic origin. They grow slowly; they may be hard with much fibro-cartilaginous tissue, or soft, and consist largely of a parenchyma varying from adult to embryonic. The former, or hard variety, are more apt to be benign; the latter malignant. They may be confused with other neoplasms, but when occurring in the parotid are so characteristic that the diagnosis is fairly certain. A microscopic section, however, may be necessary to differentiate these tumors from carcinoma and sarcoma.

Usually several years elapse between the occurrence of the growth and the operation for their removal; in the author's experience from twelve to fifteen years. Operation is usually feasible. The seventh nerve may be injured or destroyed with resulting facial paralysis, but it is fair to estimate that 75% may be radically cured. There were nine recurrences in the 56 cases operated upon at the Mayo clinic.

MALIGNANT.

Carcinoma and Epithelioma. Fortunately, primary carcinoma of the neck is comparatively rare. If a primary growth, the origin is usually in the skin, where it is under observation from the first, or a branchiogenic or thyroglossal cyst, where it is deep seated and not suspected until a considerable growth has occurred. If secondary, the primary growth will be found, or a scar following its previous removal, usually upon the lower lip, the cheeks, the tongue, the tonsils, or jaws, regions drained by the cervical lymphatics.

The primary epithelioma or carcinoma of the skin is much less common on the neck than on the face. As in other regions, it usually follows some chronic irritation or original benign skin lesions, as eczema, seborrhea, moles and cornua excrecences. They eventually ulcerate and must be differentiated from syphilis and lupus.

A careful dermatological study with the history and laboratory tests will guide us as to syphilis. The small, round, tubular nodule of lupus, with spreading ulceration and scar formation, will differentiate this lesion from cancer. The treatment is operative, the use of Roentgen rays or radium, or a combination of operation and some form of radiation. Kelly estimates that 95% of these superficial cancers are curable at a fairly early stage by radium. (Personal communication.)

The thyroglossal and branchiogenic carcinomata occur below the deep fascia of the neck more frequently in women of advanced years. Pain may be felt and is frequently referred to the ear before the tumor is in evidence. These growths may be confused with metastases or malignancy from other regions, or with chronic tuberculous adenitis, but their tendency to infiltrate and their irregularity and density are strongly suggestive of their true nature. Operation is rarely successful. Massive radiation probably holds out the only hope of cure. A case has come under the author's observation recently, where in a man of 65 carcinoma of this type has been markedly improved by the use of radium.

Secondary carcinoma in the lymph glands of the neck is not uncommon. The original growth is frequently on the lower lip, tongue, cheek or tonsils. This secondary invasion commences as a small nodule; it is hard and fixed from the first, and is a harbinger of alarming importance. With a primary carcinoma in evidence there can be little chance of error in diagnosis. Occasionally perhaps the glands may be infected with organisms of mixed infection, and some hope may be held that operation upon the original growth is not too late. Secondary carcinoma occurring after the removal of the original growth is especially hopeless.

Sarcoma. Sarcoma of the lymph glands is not a frequent occurrence in the neck; they spring from the connective tissue of the glands and tend to infiltrate early; the more cellular the more malignant they are, the small, round-celled variety being especially so. Their dense, infiltrating, immovable character impresses one at once as to their serious nature. Operation upon some of the more malignant types may hasten the vicious pathology; even securing a section may have a similar, unfavorable effect. Some form of radiation is the one hope in many of these growths.

Secondary sarcoma of the lymph glands of the neck may occur following sarcomatous invasion of the head and face; melanotic moles may metastasize to the neck. Such secondary growths, where one has knowledge of the primary lesion, leave little room for doubt in diagnosis. The prognosis is exceedingly bad under any form of treatment.

Lymphosarcoma. Lymphosarcoma is more common than sarcoma of the lymph glands. Microscopically the structure consists of lymphoid cells enclosed in a stroma. The tumor commences

Lympho-sarcoma.

in one gland, early breaking through the capsule and invading surrounding tissue. Dark discoloration of the skin with breaking down of the subcutaneous tissue follows. While other groups of glands are not likely to be involved, metastases to other organs are common. These growths may be erroneously diagnosed as abscess or chronic inflammatory lesions. They are sometimes unwisely incised. At present radium seems to offer most hope for these serious lesions. A number of cases of serious lympho-sarcoma are reported as having been entirely cured.

TUMORS OF SPECIAL ORGANS.

Thyroid: Physiologic Hypertrophy of Menstruation and Pregnancy. The period of puberty, more particularly in the female, menstruation and pregnancy, are often accompanied by congestion and appreciable bilateral enlargement of the thyroid gland. Unless excessive, this condition can hardly be considered pathologic. Undoubtedly, however, the thyroid gland is at times susceptible to unfavorable influences, as throat infection and functional irritation or stimulation of the sympathetic nervous system. Enlargement of the thyroid due to this physiologic congestion tends to subside with rest and hygiene.

Colloid Adenoma (Goitre) with or Without Cysts. The enlarged thyroid of the colloid type depends upon the increased size of the follicles which are distended by the colloid material. These follicles may coalesce and form cysts containing blood and serum, in addition to the colloid substance. Increased fibrous tissue may cause portions of them to be nodular; they may be tense or soft, unilateral or bilateral; they may be globular and well defined, or may spread across the neck a soft, compressible mass. There is little room for diagnostic error in these cases, but such is occasionally made, and cysts

Diffuse cystic goitre.

Malignant disease of the thyroid.

of other character,—lipomata and malignant disease,—are sometimes mistaken for goitre. In the absence of contra-indication most cases of this type are safely operable, especially those which are well outlined, distinctly cystic, or nodular and cystic. As a rule, operation is safe and simple and exceedingly satisfactory.

Parenchymatous Hyperplasia. The parenchymatous type of goitre is soft and succulent; the cut surface has a dark purple color. The amount of colloid, which is thinner than in the normal gland, is diminished. Thyroid enlargement may involve one or both lobes. It is less distinct in outline and usually of more rapid development than the cystic types. The enlargement may be of small proportions, and yet cause marked hyperthyroidism. In the majority of cases there is a mixed pathology, areas of hyperplasia and excess of colloid existing in the same gland. The accompanying symptoms of the condition, namely, tachycardia, tremor, prostration and weakness, with or without exophthalmos, lead the diagnostician to an inspection of the thyroid and the correct diagnosis. It is this type that calls forth most discussion as to treatment. Rest, hygiene, sedatives and a few remedies will often result in a remission of symptoms with, however, a tendency to recurrence. Ligation of afferent vessels and partial removal of the gland are required for a cure on more than 50%.

Fetal Adenoma. The adenomata of the thyroid are of the fetal and tubular varieties. The fetal type appears soon after birth; its structure is similar to the undeveloped gland. It becomes nodular and rises and falls with deglutition. The tubular resembles the fetal type closely and grows slowly; both are favorable for operation.

Malignant Disease.—Malignant disease of the thyroid includes carcinoma and sarcoma. Carcinoma of the thyroid is not common and generally develops rapidly in a previously pathologic

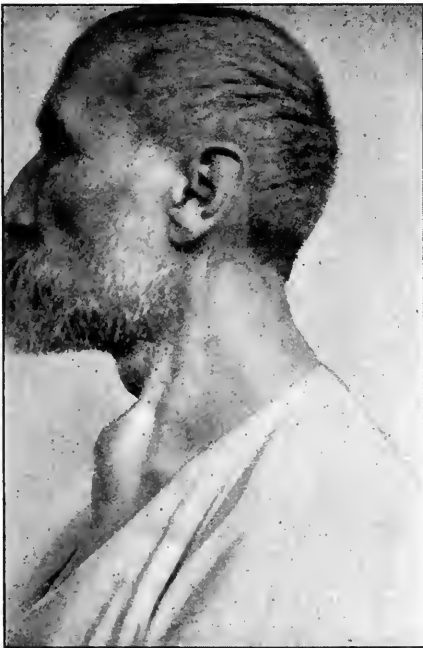

gland; it is apt to be painful and may cause dysphasia; it may be hard and irregular or soft. Involvement and discoloration of the skin and enlarged veins below the growth are suggestive of malignancy. Like carcinoma elsewhere, operation is the chief reliance in treatment, but to offer any hope of permanent cure must be performed early. Pressure on the cesophagus and trachea may call for palliative operations for relief.

Sarcoma is still less common in the thyroid and possesses about the same clinical picture. In a goitre, apparently previously benign, a sudden growth of an irregular, hard, infiltrating character, tending to involve the skin and break down, furnishes the best of evidence of malignancy. All varieties of sarcomatous cells are found in these growths; early operation is the only hope of cure.

Carotid Body. On either side of the neck, in the angle formed by the bifurcation of the common carotid artery, lies the carotid body. It is the size of a grain of rice, oval in shape, red, firm and vascular. Specific elements of the organ are said to be chromaffin, which spring from the sympathetic (embryonic) cells. They occur at adolescence or adult life in either sex. They grow slowly, but later may develop rapidly, producing pressure symptoms and a tumor of such appreciable size that a surgeon is consulted. The location of the growth, its rise and fall, with the underlying artery, the synchronous pulsation in both temporals and the slow growth, are aids in diagnosing this tumor from other neoplasms and aneurysm. These tumors have been declared benign and malignant by different pathologists. While in their early period they may be clinically benign, they are potentially malignant, taking on this character with a rapid growth later in their development. They may be mistaken for branchial cysts, lymphosarcoma

or even lipoma. The diagnosis has usually been made during operation. The operation, if performed early, may be reasonably safe and satisfactory in skilled hands, but later, when the carotid arteries and the internal jugular vein are involved, it is technically difficult and formidable, carrying a mortality of 27%.

Aneurysm of Aorta and Carotids. The development of a soft, smooth, pulsating tumor along the line of a large artery, movable laterally but not longitudinally, carrying an increased bruit to the ear from that of the vessel below, suggests at once an arterial aneurysm. Carotid aneurysms occur in the ratio of one to twenty of other aneurysms. Aneurysm of the thoracic aorta is five times as frequent as that of the abdominal aorta. The condition of the other arteries, the presence of luetic symptoms, and the luetin or

Aneurysm of common carotid artery developing one year after sub-sternal thyroidectomy.

salvarsan test are valuable diagnostic aids. It is said, however, that diagnosis of aneurysm has caused more distinguished mistakes than almost any other lesion; no radical operation has been successful upon aneurysm of the aorta. The wiring operation of Prof. Halsted is alone permissible; for the carotid, ligation and aneurysmorrhaphy are the possible procedures.

This review has been necessarily hasty and incomplete, but it is hoped that it may stimulate interest in tumors and infections of the neck, and that our efforts at accurate diagnosis in this field will be increased.

RENAL INFECTIONS.

BY WILLIAM H. ROBEY, JR., M.D., BOSTON,

Instructor in Medicine, Harvard Medical School; First Assistant Visiting Physician, Boston City Hospital.

SOME years ago, I failed to make a diagnosis in a case of pyelitis seen in consultation. My examination was thorough enough except in one particular—I did not examine the urine but accepted the statement of the attending physician that it was negative. Doubtless some specimens of the urine were negative, but had a careful sedimentation been done, the pus cells would have been found and an explanation offered for the fever and chills from which the child suffered. Since my mistake, pyelitis has been much on my mind.

While the cause of much interest and writing on the part of genito-urinary surgeons, renal infection is a disease which the general practitioner should have constantly in mind since it may be mistaken for tuberculosis, typhoid fever, malaria, appendicitis or any other febrile disease. If the urine contains considerable pus, the diagnosis of cystitis may be made and the patient fruitlessly treated for this symptom month in and month out. Cystitis is generally a symptom and unless the diagnosis has been confirmed by cystoscopic examination should be classed with such meaningless terms as "indigestion" and "rheumatism," and should not be accepted as a disease any more readily than pain in the abdomen, headache or irregular pulse.

The degree of involvement of the kidney and the intensity of the infection make the disease present itself in a variety of ways. A cessation of symptoms may lead the physician to think that he has cured the disease whereas better drainage and improved health have merely held the symptoms in abeyance. It is well recognized that some cases of pyelitis involving the pelvis alone and not caused by a foreign body will recover, but others where the process is no deeper, may pass on to the chronic stage, undergoing acute exacerbations from time to time. This depends largely on whether the pelvis empties itself or not. In all cases of pyelitis where improvement is not speedy nor lasting, it is our duty to search

out the etiology by special examinations of radiography and cystoscopy.

Pyelitis is an acute febrile disease characterized by the presence of pus in the urine. Pain and sensitiveness to pressure or a feeling of pressure are often the first symptoms, although they may be entirely absent. If there is a calculus or a plugging of the ureter there may be a typical renal colic. On the other hand, if the intrarenal pressure is not much affected and the drainage good, the local signs may be entirely wanting, although the urine may show macroscopic or microscopic pus, and there may be the constitutional signs of toxemia. Several specimens of urine may not show pus when the condition is unilateral, due to temporary blocking of the ureter, and of course while this lasts it is apt to confuse the diagnosis. It is clear that repeated and careful examinations of the sediment are necessary. Along with the pain in the lumbar region one may be able to detect some swelling of the kidney by careful bimanual palpation.

Pain, sensations of pressure, swelling by bimanual palpation may be greatest when the urinary findings are smallest, because of increased intrarenal pressure and poor drainage.

The most common symptoms are chills, fever, sweats, loss of weight and strength, general physical depression and digestive disturbances. In most of the cases I have seen the two signs which have stood out apart from the general constitutional disturbance have been tenderness in the kidney and pus in the urine. Even when the symptoms are very slight, this tenderness is more or less persistent.

The pus in the urine may be readily seen or it may require careful sedimentation. There may be casts indicating a pyonephritis although casts may appear for a time when the intrarenal pressure is great. On the other hand, there may be a pyelonephritis without the presence of renal elements.

The organisms responsible for the infection are the colon bacilli in the great majority of cases. R. M. Smith quotes Jeffries (*Quarterly Med. Jour.*, 1911, iv, 267) in a report of 121 cases, 67 were colon, 37 staphylococci, 10 streptococci, 3 pneumococci, and 4 miscellaneous. Channels of infection need not be considered more than to say that it may be an ascending infection by the ureter, although this source is doubtful, or the kidney may be involved through the lymphatics in the course of a general infection.

The treatment of pyelitis depends upon early diagnosis, which in turn depends upon a determination of etiology. Etiological factors are roughly divided into two groups: first, those that lower the resistance of the kidney by producing retention of urine by trauma or pressure congestion; second, by infection, direct, metastatic or ascending. Many of the acute cases recover spontaneously, while the chronic forms may resist all treatment. If there is not a prompt response to medical treatment a thorough search should be made for the reasons.

Pyelitis is a disease which may require medical or surgical treatment or both, and it is the duty of the practitioner to his patient and himself to determine the proper course as soon as the facts will permit.

Prophylaxis is very important:—

1. Remove, if possible, all causes of urinary stasis, such as urethral stricture, phimosis or hypertrophied prostate. Actual bladder tumors, ulcers or foreign bodies, can be discovered only by the cystoscope.

2. Care in catheterization, especially where catheterization must occur frequently, as in typhoid fever and after severe labors.

3. Flushing the kidneys in severe febrile diseases and in pregnancy.

4. Raising the general resistance of the patient.

5. In children, especially since many more cases occur in girls than boys, care should be taken during the diaper age.

If the condition becomes chronic a bacteriological search should be made and the urinary tract examined by the radiograph and the cystoscope. These examinations are safe only in the hands of experts since the technic and the interpretation of the findings are difficult.

Treatment is a broad subject from an etiological standpoint, but with the source of the infection defined it narrows down considerably. Some laboratory men who are enthusiasts in the use of vaccines believe that they have cured an occasional case, but in offering the treatment they certainly hold out very little encouragement. In the few cases in which I have tried them the results have been nil. Lyman (*North-west Med.*, 1911, iii, 31) says that vaccines are of great value, but adds "many cases do not improve more rapidly than others without it."

In the acute cases there seems to be the greatest uniformity of opinion that the urine should be made alkaline and kept so for a considerable period of time and that free diuresis should be established. Colon bacilli are believed to develop less easily in an alkaline urine and phagocytosis of the bacilli by the leucocytes is more active in an alkaline medium. (Dick, *British Med. Jour.*, 1910, ii, 1134.)

Potassium citrate or sodium bicarbonate are the drugs most commonly used for this purpose.

Betz (*Deutsch. Arch. f. Klin. Med.*, November, 1912) is directly opposed to this view, and believes that the thin, weakly acid urine occurring normally in pyelitis is the most favorable culture medium for the colon bacillus but that it is unable to proliferate in a very acid, concentrated urine. He gives phosphoric acid and a meat and non-vegetable diet in order to make the urine strongly acid, limits the intake of fluids and gives hot air baths to produce concentration.

Calomel, ammonium and sodium benzoates, sandal wood oil, salol and urotropin are among the drugs recommended. Whatever is used, the antiseptic should be changed frequently. The action of hexamethylenamin depends upon its

liberation of formaldehyde, and it has been shown that this occurs only in an acid urine. Some combine hexamethylenamin with alkalies like potassium citrate, thus producing unsatisfactory results.

Raising the general health of the patient is important as in all other infections.

If by cystoscopy and radiography, tuberculosis, abscesses, foreign growths, calculi or a hydronephrosis are found, then the treatment becomes surgical.

The following cases occurred in hospital and private practice:—

CASE 1. S. T., 55 years, married. Entered the hospital, June 15, 1914.

P. H.—Negative. No early diseases remembered. Cough for last two years "caused by a tickle in the throat"; no sputum. Bowels regular.

P. I.—For the last two years spells of coughing, with "dry heaves" in the morning.

Began to be tired all the time and to have pain in the legs. The bowels became irregular. No pain at any time in the abdomen, but for the last three months has had distress in the epigastrium after a heavy meal. About the same time discovered a mass in the left lower quadrant which seems to vary in size, but on the whole not to be growing larger. Belly often full of gas. For seven or eight weeks there has been a severe aching pain across the lower part of the back at night. Slight dyspnea on exertion. The urine was "milky"; stains the sheets yellow and "starches" them. Lately has felt better. Three years ago weighed 135 pounds, now 116.

P. E.—Generally negative except in the left abdomen under the costal margin there is a bulging with dullness. In this area is a tumor, size of a large grape-fruit with firm smooth edge, slightly tender on palpation with movable nodules over the surface. Tenderness in the left costo-vertebral angle. Liver and spleen not palpable. On deep inspiration the upper edge of the mass could be differentiated from the spleen. Temperature was never higher than 99° F.

The tumor remained unchanged by moving the bowels with oil enemata. White count, 18,000. Hg., 85%.

Urine: Generally pale, average sp. gr. 1.008; albumin ranging from absent to a slight trace. Every sediment showed considerable numbers of leucocytes and cystoscopy showed a large amount of pus. The Wassermann was triple positive.

The diagnosis of infected kidney was made at once. From the age of the patient with loss of weight and strength, malignant growth was considered, but after a few days in the hospital the general improvement was marked. There was no cachexia. Operation was necessary, but whether for pyonephrosis, hydronephrosis or calculus was not clear. At operation the kidney was found to be increased to about three times its normal size and was trabeculated with many cavities filled with a pea green pus, having a sweetish, not unpleasant odor. These were the pus cavities which we felt as nodules before operation. In the lower pole was found a calculus. Unfortunately the pus was not studied bacteriologically. The patient made a good recovery.

CASE 2. A. M., entered about the same time, 19 years, unmarried, a stitcher. *P. H.* was good, no tubercular history.

P. H.—Morbili; parotitis as a child. Fleeting pains in the shoulder and other joints at times. Micturition four or five times in the day and one to four times at night. No burning.

P. I.—Five weeks ago awoke in the night to find that the left shoulder was tender, hot and painful on motion. It became worse during the following days, but there were no constitutional symptoms. Four weeks before entrance had a sudden sharp pain in the left hip, not radiating, followed by a steady dull pain, which has persisted. Two weeks ago a swelling on the outer aspect of the left arm, which broke down two days ago and pointed. Eight years before the right knee became painful and stiff, and after a week was operated on at the Children's Hospital.

P. E.—Negative except for abdominal tenderness in left lumbar region and costo-vertebral angle. No tumor made out; liver and spleen not felt.

Left thigh held flexed and motion limited by pain due to pull on abdominal muscles. No ankylosis nor tenderness in hip joint. No edema. Knee-jerk present on the right. Fluctuating tumor in upper third of left arm, not connected with the shoulder joint. White count, 18,000 to 22,000. Average temperature in the morning 99° F., 102° in the evening.

Urine in each examination showed a trace of albumin, occasional hyaline and granular cast; many red and white cells. The x-ray examinations of left hip and arm were negative.

It was thought at first that this was a tubercular hip, but the negative radiographs ruled out this possibility as well as psoas abscess, which was also considered. The pain in the costo-vertebral angle and the constant appearance of pus in the urine pointed to a kidney infection.

At operation the condition was found to be a perinephritic abscess; incision and drainage with satisfactory recovery.

CASE 3. M. W., 17 years, single; paper sorter; admitted to the Boston City Hospital, August 11, 1914.

P. H.—Negative.

P. H.—"Never sick in my life." Sore throat in winter for the past two years. Abscess of the scalp three weeks ago.

P. I.—Six days ago had anorexia, feverishness and pain in the small of the back. Buzzing in the right ear without pain. Paracentesis by a local doctor; red-tinged discharge. Diarrhea for two weeks. Since onset some burning during micturition and nocturia two or three times.

White count, 7000. Urine: pale, slightly cloudy. many pus and small round cells.

This was probably a pyelitis resulting from a general infection or a focus in the scalp or post-nasal space.

Under urinary antiseptics and rest in bed, the condition gradually improved.

CASE 4. M. J. B., 45 years, married, entered Boston City Hospital Oct. 22, 1914.

P. H.—Negative.

P. H.—Scarlatina at 7 years of age; one child 14 years ago.

P. I.—More or less irregularity of micturition since birth of child. July 5, 1914, went to bed with soreness in the right flank. Severe chills for two days followed by fever and prostration. Remained

in bed for five weeks with more or less irregular temperature and anorexia; backache and slight burning during micturition. At that time the condition had the appearance of typhoid fever, although the temperature was not characteristic and the Widal test persistently negative. After that she was up but in a state of invalidism.

I saw her in consultation Sept. 9, 1914, with Dr. H. V. Reynolds.

Except for a palpable, slightly tender, but not enlarged right kidney, the physical examination was negative. The Hgb. was 70%. White count, 10,000. The urine showed a very slight trace of albumin with moderate sediment containing pus free and in clumps and a few squamous, caudate and large round epithelial cells; very rarely a highly refractile cast and a coarse granular cast. No blood.

A catheter specimen from the bladder gave many colonies of colon bacilli. From these cultures a vaccine was made but the patient gave no signs of improvement from its use.

On Oct. 20 I saw her again and advised admission to the hospital for radiography and cystoscopy. Both of these examinations were negative. With rest in bed the general strength and digestion markedly improved. Since no pus was obtained from the right ureter during catheterization it would raise the question whether this case had gone from pyelitis to pyelonephritis, since the renal elements persisted after the intrarenal pressure was apparently reduced. As to the diagnosis of typhoid fever which was made in July, I have seen this mistake several times. Typhoid has a temperature which generally rises gradually and is then maintained, whereas the temperature of pyelitis undergoes greater excursions in the twenty-four hours. In this case the Widal test was persistently negative, while in typhoid it occurs at some stage in the disease in over 95% of the cases (McCrae).

If chills persist, as they often do in pyelitis, they should suggest some disease other than typhoid. Rose spots are very apt to appear in crops in typhoid and the mental condition becomes dull; neither appeared at any time in this patient. As to the subsequent treatment of this patient, the negative findings by special examinations make us confident in proceeding along general lines by giving urinary antiseptics and increasing the patient's tone.

CASE 5. A. G. L., 46 years, married, housewife.

P. H.—Good.

P. H.—Never very strong. In 1905 had an operation for the removal of an acute appendix and since then has had a number of attacks of so-called "inflammation of the bladder."

P. I.—In 1911 this patient had an attack of painful micturition with small amounts of pus in the sediment. With rest and the use of various urinary antiseptics the condition gradually quieted down. In September, 1912, another similar attack. There was pain in the right flank and the kidney was tender on palpation but not enlarged. The urine showed a very slight trace of albumin and the sediment contained a moderate number of pus cells. Dr. A. L. Chute saw her in consultation. He made the following report: "In the first place I could find no organisms in smears made from the sediment of the bladder urine. When there is a lot of pus, that

is suspicious of tuberculosis; when there is only a little as with Mrs. L., it may simply mean a run-out culture of some common pyogenic organism. In several slides that I used a differential stain upon, I was not able to find any acid-fast bacilli. I found a little pus coming from her right ureter; practically none from her left." "I believe her trouble comes from a dilated kidney pelvis on the right and that it constantly harbors some organisms that would be evident on culture, though I do not find them in smears. That from time to time it flares up and then she has her acute attacks with secondary involvement of the bladder and the symptoms referred to the bladder."

A few weeks prior to this attack, Mrs. L. had a cough with a doubtful area of consolidation in the third space on the right front. This, with the fact that she had lost some in weight and strength made me fear tuberculosis. Dr. Chute inoculated two guinea-pigs, one with a catheter specimen from the right kidney, the other from the left. At autopsy both pigs were entirely free from tuberculous lesions.

Dr. Percy Brown made radiographs of the kidneys; the pelves did not seem to be enlarged and there were no calculi. The only abnormality that could be found by radiograph was a slight kink in the right ureter and after the injection of collargol the pyelitis quieted down. The patient was comfortable for a little more than a year. She felt so well that she began to overtax her strength when she had another attack of pyelitis, not so severe as the one I have just described.

In this case we must follow the same line of treatment as in the one M. J. B. Having ruled out as carefully as possible conditions indicating operative treatment we are justified in planning a medical course which will as much as possible hold the infection in check.

CASE 6. C. V., 28 years; married; farm work.

P. H.—Negative.

P. H.—Difficult to obtain. Three months pregnant.

P. I.—Entered the Boston City Hospital July 11, 1914. Four days prior to entrance went to bed having a severe constant pain in the left flank. The left leg was partly flexed and could not be fully extended without causing great pain. Slight malaise but no cough, dyspnea, palpitation or edema. No nausea, vomiting or abdominal pain. Pain during micturition; rarely nocturia. The expansion of the right chest was greater than the left and there was a definite swelling with fluctuation above the left iliac crest. The urine was free of albumin and the sediment contained a few pus cells and large round cells. No blood and no casts. The morning temperature was normal, the evening averaged 104° F. This tumor increased so rapidly in size and tenderness that through a *faux pas* she was operated upon before the radiograph which showed several renal calculi was finished. A perinephritic abscess was drained and the patient was discharged relieved, having refused, much to my regret, but not my surprise, to consent to a second operation. The abscess contained green pus similar to that found in the case S. T.

CASE 7. R. R., 11 years, female; seen in consultation with Dr. Charles L. Knight. Always well, but a tall, thin, delicate looking girl.

P. I.—Very sudden onset with chills, sweating and temperature ranging between 103 and 105° F. General physical examination negative except for the most marked tenderness I have ever seen over the kidney in a case of pyelitis in a child, so marked that perinephritic abscess was considered at once. The urine was filled with pus and blood, but with the free use of hexamethylenamin the condition quieted down in a week. In four months she has had as many similar attacks much less severe. As it is, the child is in a state of invalidism and the family has objected to the more searching methods of diagnosis which Dr. Knight has proposed. Such a waste of time in making a correct diagnosis we feel to be entirely unwise.

In conclusion, a report of these infections by a medical man seems not inappropriate since practitioners are the ones who must first see them, and upon their promptness in making a diagnosis, based on a careful etiological survey, depends the outcome.

Cases of pyelitis of tuberculous origin should not be allowed to continue until the bladder is involved.

Renal infection must be considered in the differential diagnosis of every febrile affection.

The urine may show much or little according to the degree of intrarenal pressure and drainage and the condition of the ureter, so that frequent and thorough examinations of the sediment are necessary.

The two most constant signs are pus in the urine and some degree of tenderness in the kidney by bimanual palpation.

I desire to thank Dr. Arthur L. Chute for several suggestions and the other physicians mentioned for the privilege of reporting their cases.

Clinical Department.

A CASE OF HUMAN RABIES.*

By HARRY LINENTHAL, M.D., BOSTON,

Physician to Out-Patients, Massachusetts General Hospital; State Inspector of Health.

THE following case of rabies which was observed closely from the time the patient was bitten through the development and termination of the disease, presents many features of interest and a detailed report of it is justified. The patient received a full course of intensive Pasteur treatment without developing an immunity. Moreover, the quinine treatment which Harris¹ reported to have cured a case, was tried without avail in this case, equally unavailable was a new method of treatment tried.

* I am indebted to Dr. C. Frothingham on whose service in the Peter Bent Brigham Hospital the case was admitted and to Drs. F. B. Grinnell and R. Kohn of the Department of Preventive Medicine of Harvard Medical School who followed the case with me.

M. C. N., twenty years of age, was bitten by a stray Scotch collie in the left thumb while walking in the street on the morning of July 25, 1914. The wound consisted of a slight longitudinal superficial abrasion of the distal phalanx of the left thumb and a punctured wound at the root of the nail into the matrix.

The dog did not, as far as could be learned, attempt to bite any one else but remained quietly on a near-by lawn till he was shot by a police officer about two hours later. As is unfortunately too often the case, the carcass was disposed of without an examination of the brain being made.

After being bitten the patient immediately reported to his family physician, who bathed the thumb for twenty minutes in 1:1000 corrosive sublimate solution and applied a corrosive dressing. The dressing was removed on July 27 and the wound was practically healed.

Several days later the case was brought to the attention of the State Department of Health by the family, who asked that Pasteur treatment be administered. Virus was obtained from the Hygienic Laboratory of the Public Health Service in Washington and on Aug. 1, seven days after the patient was bitten, the treatment was started.

The course of the treatment was uneventful with the following exceptions: On the seventh day of the treatment there was a very slight local reaction without constitutional disturbance at the site of the first injection. This cleared up in twenty-four hours. On the ninth day there was a slight local reaction at the site of the injection of the previous day. This reaction lasted less than twenty-four hours. On the thirteenth day of the treatment the patient complained of headache and nausea. The headache persisted for several days, during which time, however, his temperature remained normal. The treatment terminated on Aug. 21 and the patient was discharged, feeling in his usual good health. He was instructed to report from time to time as to his condition so that we might keep in close touch with him. He was cautioned to avoid any excessive physical exertion, to avoid exposure to cold and alcoholic beverages.

On the afternoon of Sept. 8, eighteen days after the completion of the Pasteur treatment and forty-five days after he was bitten, he began to feel a numbness of his left thumb, which during the night extended up to his elbow; in addition to the numbness he experienced from time to time a sharp stinging pain shooting down his left forearm. An examination made on the morning of Sept. 9 was entirely negative. He appeared in his usual good health, his deep and superficial reflexes were normal, and there were no sensory disturbances in his left thumb and forearm, the site of the numbness. The subjective feeling of numbness was much less than on the previous night. He reported that since the termination of the Pasteur treatment on Aug. 21 he felt well, his appetite was good, his bowels were regular and he slept well. He was kept under observation all day but nothing developed. The next day the patient's mother reported by telephone that he had a sleepless night and that he was not feeling well generally. In order to keep him under constant observation and to have him near where he could be easily reached, arrangements were made with the Peter Bent Brigham Hospital, where he was admitted on the afternoon of Sept. 10. On admission he was found to have a slight elevation

of temperature, otherwise the examination was entirely negative.

On Sept. 11 the numbness had diminished except when the thumb where he was bitten was pressed. His neck seemed a little stiff, but with distraction of patient's attention it could be easily moved. His reflexes were normal. There were no Kernig and no other signs suggestive of meningeal irritation. Heart showed a slight respiratory arrhythmia. Slight elevation of his temperature persisted.

His urine was straw colored, acid in reaction, 1.009 specific gravity and except for a slightest possible trace of albumen was negative.

An examination of his blood showed a white count of 14,000, of which 57% were polynuclears, 26% large mononuclears, 17% small mononuclears, erythrocytes not remarkable.

On the morning of Sept. 12 the patient complained that his ears were particularly sensitive to sounds. He was distressed by the ordinary sounds in the ward so that he had to place pieces of cotton in his ears. He also complained of double vision. Examination showed marked diplopia when focusing on an object two feet away; marked nystagmus particularly when eyes turned to right. Paresis of right external rectus. All superficial and deep reflexes were present. The plantar was present on the right, on the left the normal plantar was absent but there was a contraction of the fascia lata when the sole was stimulated. There were no Babinski, Oppenheim or Gordon reflexes, no Kernig and no neck sign.

At 1.30 in the afternoon of Sept. 12, the patient had a moderate chill, there was a marked general hyperaesthesia with increased response to stimuli of all kinds. Photophobia became extreme. There was dilatation of the right pupil though it reacted to light. The muscles of the eyelids twitched continually and there were also occasional slight twitchings of the muscles of the arms, more marked on the right side. He complained of a choking sensation and began to raise large quantities of saliva. His respiration became jerky and sobbing in character and spasms of the muscles of deglutition became pronounced. He would make quite elaborate preparations before taking a drink, such as clearing his throat, changing position, etc., he would then take the water in his mouth and hold it there for several seconds; then he would make a sudden effort to swallow it, bringing on severe spasm. He was given a gram of chloral and fifteen mgms. of morphia, which quieted him somewhat.

His mind was perfectly clear during the afternoon; towards evening he became mildly delirious, was rather talkative, though well oriented.

At eight o'clock Dr. I. C. Walker administered 14 c.c. of salvarsanized serum intraspinally. Fifteen minutes later he was given 1 gm. of quinine and urea hydrochlorate intravenously. There was an immediate violent reaction to the intravenous injection, the patient's face became flushed and dusky, he broke out in a profuse perspiration and within one minute after the injection he complained of intense buzzing in his ears. His pulse became somewhat accelerated and he was distinctly uncomfortable. His condition steadily grew worse, so that in view of the intense reaction to the quinine no more was administered. About midnight he became noisy, delirious and irrational and was restrained in bed with difficulty. He had hallucinations of dogs chasing him. Several doses of morphia and atropine were given to him with little effect. The patient gradually be-

came weaker and died at 4.20 a.m. on Sept. 13 of respiratory failure.

The spinal fluid, 25 c.c. of which was withdrawn at the time the intraspinous injection was given, was slightly cloudy, forming a delicate filamentous clot on standing. There were 600 cells per cmm. of which 40% were polymorphonuclears, 20% small lymphocytes, 38% large lymphocytes and 1% endothelial cells. No plasma cells. Wassermann negative. Dr. F. B. Grinnell injected $\frac{1}{2}$ c.c. of the fluid subdurally into each of four rabbits; none of them came down with the disease.

MORTALITY FROM RABIES.

The incidence of rabies from bites of rabid animals as compiled in different statistics shows considerable variation. It depends upon the age of the person bitten, the severity of the injury and the location of the bite, the nearer the head the more likelihood of the development of the disease. From the statistics compiled by various writers it would seem that about 16-20% of persons bitten by rabid animals develop the disease.

Once the symptoms of the disease develop the termination is almost invariably fatal. Some aborted types of the disease have been reported as well as recovery after symptoms have developed, but the diagnoses in such cases have been questioned. It is safe to state that if recovery occurs the disease was almost to a certainty not rabies.

Pasteur treatment has reduced the mortality from the bites of rabid animals to about 1%. Not all deaths from rabies among those taking the Pasteur treatment, however, can be regarded as due to the failure of the treatment. The establishment of an immunity to rabies by the injection of attenuated fixed virus is a slow process requiring three weeks. Fortunately the incubation period of rabies is usually a long one so that there is sufficient time to establish an immunity. Some cases, however, have a short incubation period, and the disease develops before an immunity can be established. Such cases cannot be regarded as failure of the treatment. That certain individuals, however, will fail to develop an immunity by the treatment is shown by the occasional development of the disease long after the treatment has been completed.

In this case eighteen days elapsed between the completion of the treatment and the onset of the symptoms, a time sufficiently long to establish an immunity if the treatment were effective. This case must be regarded as one of the rare failures of the Pasteur treatment.

TREATMENT OF RABIES.

In 1913 Moon² published experimental results with the use of quinine in the treatment of rabies in dogs. Dogs to whom quinine sulphate was administered recovered from rabies while those who did not get the treatment died from the disease.

In October of the same year Harris¹ reported a case of human rabies which recovered after the intravenous administration of quinine and urea hydrochlorate. The experimental results of Moon have not been confirmed by Frothingham and Holliday and by Cummings. Nor has quinine proved efficacious in two cases of human rabies reported since the publication of Harris's report. The case reported here must be added to the other cases unsuccessfully treated with quinine.

Salvarsan and neosalvarsan have been used unsuccessfully in the treatment of the disease. As far as I can find, this was the first time salvarsanized serum was used intraspinally, but unfortunately with no success.

PUBLIC HEALTH ASPECT OF RABIES.

I have had the opportunity to see two cases of human rabies within a few months. The case not here reported I saw in the terminal stage of the disease. The patient, a man of 45, was bitten by a dog six weeks previous to the development of the symptoms. The dog was killed by a police officer and the carcass disposed of without an examination being made. No Pasteur treatment was given.

To see a case of human rabies is sufficient to make one wish never to have to see another one. The pity of it all is that this most horrible of diseases is preventable. What can be accomplished by preventive measures can be seen by what has been achieved in Australia and England, where by the simple muzzling of dogs the disease was entirely eradicated.

In the nine-year period 1905-1913 inclusive, twenty-five deaths from rabies have been reported in Massachusetts. We must assume the responsibility for the inexpressible physical and mental suffering of those afflicted, for the agonizing states of mind of the families and friends of the victims, and for the anguish and anxiety of those bitten who undergo the treatment. This dreadful disease exists with our consent and its victims die with our approval.

Medical Progress.

REPORT OF PROGRESS IN MENTAL DISEASES.

PART I.

By HENRY R. STEDMAN, M.D., BROOKLINE, MASS.

PARAPHRENIA.

UNDER this head Kraepelin¹ separates from dementia precox a new group, still employing the

criterion of the final outcome. He says that in dementia precox the disorganization of the psychic personality affects chiefly the affective life and will. The paraphrenic group, a small one, in spite of manifold points of accord with the manifestations of dementia precox yet has far less influence upon the affects and will, and consequently results in much less disturbance of the inner character of mental life. The main disturbance here is with the intellectual functions. These patients even in the last stages do not show the affective dulness and indifference which represent so frequently even the earliest signs of dementia precox. The actions and conduct are in the essence affected only by the abnormal trend of thought and mood. "Independent disturbances of the will," which tend to accompany dementia precox in such manifold form (e.g., mannerisms, impulsive acts, stereotypies, etc.), occur here only exceptionally.

(1) *Paraphrenia Systematica*, characterized by the insidious onset of steadily growing delusions of persecution, with later ideas of grandeur but without destruction of personality. The disease takes years to develop; ideas of reference and sense-falsifications play a considerable part in its evolution. The delusions are well systematized and may be accompanied by memory falsification. There seems to be no end-stage as the disorder continues progressively throughout life. Recovery does not occur, but it is especially emphasized that there is no loss of interest.

The close resemblance of this picture to that described by others under the title of paranoia needs but little emphasis. In speaking of the relation of paranoia to dementia precox Kraepelin claims that there can be no difficulty in distinguishing between the two because of the absence in the former of any evidence of independent disturbances of will or of signs of affective deterioration. This distinction seems hardly to hold good with regard to paraphrenia systematica and we must await the appearance of the volume dealing with paranoia for enlightenment.

(2) The *expansive type* characterized by the rich development of grandiose ideas, generally with heightened mood and some slight excitement. This is an extremely interesting, though small, group composed almost entirely of women, and the cases have hitherto been usually classed with the manic-depressive disorders, as was done by Kraepelin himself, or with paranoia. The disorder is of slow progressive evolution and like the last, reaches no end-stage and presents little or no loss of interest.

(3) *Confabulating form*, very similar to the last, but characterized by the development of very marked memory falsifications.

(4) *Paraphrenia Phantastica*. Under this name are included the small group of cases originally classed as dementia paranoids. They are characterized by the development of the most phantastic and incoherent delusions. Beliefs are elaborated and maintained which seem to surpass

the boundaries of possible credence. In this type again evidences of disorder of affect and will are more or less absent.

The separation of these types of "paraphrenia" from dementia precox is based upon the absence of affective and volitional deterioration and also upon the progressive course which seems to lead to no final end-stage. The step is unquestionably consistent with Kraepelin's general principle that the end-results represent the character of the disease process and it has the further advantage of removing some of the difficulties experienced by those who regard dementia precox as a destructive brain disease. With Kraepelin we must be content to await further study to determine the justice of the step, and so long as we do not allow ourselves to be entangled in the enticing web of exact classification and regard dementia precox, paraphrenia and their various subtypes as established disease entities we may be grateful for the clear delineation of clinical facts.

THE ABDERHALDEN TEST IN MENTAL DISEASE.

Simon² takes up the claim of Fauser as to the findings of the Abderhalden test in certain types of insanity with special reference to dementia precox. In surveying the literature one cannot help being impressed, on the one hand by the wonderful uniformity of the results reported by Fauser and the wide divergence from those of certain other authors, like Hauptmann and Bumke. He thinks that there is good ground to suspect that Fauser was too enthusiastic in his views and also that his opponents may have lacked complete control of the technic. Fauser himself states that he obtained reaction with sex gland repeatedly in cases in which it was unexpected and that the diagnosis between manic-depressive insanity and dementia precox could not always be made with certainty. Simon relates his own experience with the use of the test in 106 cases and says, "to summarize the results" that a sex gland reaction may be obtained in nearly if not all cases of dementia precox at some stage or another, but that this action may also be obtained in other forms of insanity, and does not attempt to explain them. He must, therefore, conclude that Fauser's rule has exceptions or that the positive findings in manic-depressive insanity or paresis are due to errors of diagnosis or technic. The fact, however, remains that in dementia precox the positive reaction is the rule, while in the purely functional psychoses it is the exception. Simon, therefore, discusses at length the technic employed and which he thinks meets fairly any criticism from the technical point of view as far as our knowledge goes at present. He believes, however, that advances can still be made, and while we cannot, as yet, draw positive conclusions regarding the significance of the reaction in dementia precox, certain possibilities suggest themselves. One of these is that of a secretion of the sex glands in dementia. "Consid-

ering the problem from the clinical side, the all-important question of course suggests itself, whether or not the reaction has any relation to the pathogenesis of dementia precox. Theoretically, this is, of course, perfectly possible. Granted that anti-sex gland ferments do occur in the circulation in dementia precox, and that their presence was the outcome of the appearance in the circulation of an abnormal secretion or of abnormal cells, then we may also assume that digestion of these cells or cell-products will take place, and that all conditions would thus be given for a chronic protein intoxication which might very well expend itself on the central nervous system. Should this be true, then we might also expect that the administration of sex gland to such patients would cause an aggravation of the patient's condition, while partial or entire castration, possibly combined with the transplantation of normal organs, might similarly be expected to have a beneficial influence. Evidently, the problem is now open to investigation from many sides, and it does not seem unreasonable to expect that definite advances will be achieved in the near future."

Orton,³ concluding a careful critical digest of the literature bearing on the Abderhalden method, reviews the situation as follows: Many defense enzymes are reported in cases of organic psychoses which are not found in normal controls or in any number in the strictly functional psychoses. In the great majority of dementia precox cases the ferments reported are those against brain or the sex glands, or the two combined. When sex gland reactions occur they follow a strict sex-specificity, *i.e.* male sera react to testicular extracts, but not to ovarian and vice versa. In a smaller number of cases of dementia precox thyroid dysfunction, either by itself or associated with brain and sex gland, is recorded. Cases do occur, however, in considerable numbers in which these so-called characteristic reactions are lacking and the same reactions have been found in other psychoses, notably general paralysis, and, by one investigator, in idiocy. This in itself he considers sufficient to preclude considering the test as of great value as a diagnostic means, until further refinements of technic or larger series of carefully studied cases have been reported. The application at present to border-line cases for the purpose of diagnosis or the altering of clinical diagnosis on the ground of serological findings seems unjustifiable, as the clinical study of the case must still be considered the means of control of the specificity of the reaction. Further studies should include also better classification of cases than simply dementia precox, and preferably short abstracts of the clinical features of the case. The results of one or two investigators seem to indicate that variations may occur in different stages of the disease, *i.e.* negative reactions in terminal cases and differences between the various types.

Even if we accept the theory and the results

of the most hopeful investigators, we are only brought to the beginning of a wider field of investigation, as by the interpretation of the theory the results speak only for a faulty metabolism in specific organs and as yet give no light on the underlying causes, *i.e.* the fact that the metabolism of the testicle and brain are disturbed gives no insight into the cause of such disturbance.

THE COLLOIDAL GOLD REACTION IN EXAMINATION OF THE CEREBROSPINAL FLUID.⁴

The importance of the colloidal gold reaction, otherwise known as Nonne's or the gold chlorid test, has been recognized for some time, but until recently few have known within what limitations its value lay. It is essentially a test for an increase in the globulin content of the cerebrospinal fluid, using delicate color reactions in a standardized solution of colloidal gold as an indicator. The requisites for the test are cerebrospinal fluid obtained without a trace of blood, scrupulously clean glassware, and a colloidal gold solution prepared with extreme care. With these essentials at hand the performance of the test is comparatively simple. Miller and Levy⁵ give explicit directions for preparing the solutions and performing and interpreting the results, together with an extended series of observations in which the results of the Wassermann test on the blood and cerebrospinal fluid, cell and globulin estimation on the fluid and the colloidal gold reaction are compared in a great variety of clinical conditions. These tables show that normal cerebrospinal fluid gives negative reactions, but that in inflammatory conditions of the meninges, as tuberculous and purulent meningitis, the test is positive; hence it is of no value in distinguishing between these and syphilis. The reaction is inconstant in secondary and tertiary syphilis, and has no advantages over other diagnostic procedures in these conditions. The evidence seems to show that colloidal gold reaction is most constant in general paresis and hence will be found of most value in the differentiation of this condition from others with which it might be confused. The authors suggest that this test may be found more sensitive than others now employed for indicating the results of specific therapy in syphilitic diseases of the central nervous system. The report is an example of what should be done with every new procedure either curative, prophylactic or diagnostic. Tests should be made in large numbers of diverse conditions and conservative conclusions drawn from the results as to the value and limitations of the procedure in question.

THE CATATONIC SYNDROME AND ITS RELATION TO MANIC-DEPRESSIVE INSANITY.

Kirby⁶ states that according to Kraepelin, all non-organic cases with catatonic symptoms belong to the dementia precox group, and such

manifestations were looked upon as significant of a deterioration process. Kraepelin, of course, admits that about 13% of the catatonics appear to recover, but the permanency of these recoveries he regards as unsettled, and inclines to the view that they are probably only remissions. Wilmans later reviewed Kraepelin's own Heidelberg cases, and found the catatonic symptoms, as evidence of a deterioration process, had been greatly overrated.

The catatonic syndrome is not a clinical unit, and it is probable that deteriorating and non-deteriorating catatonic cases represent fundamentally different reaction types. A review of a large material has shown that in acutely developing catatonic states, when not preceded by any ominous prodromal symptoms, recovery, with few exceptions, takes place, and in some instances after a duration of several years.

The possible relation of these acutely developing catatonic states in relation to manic-depressive insanity is discussed, because the subsequent history of such cases shows not infrequently manic attacks. Four such cases are described. The most reliable prognostic data in all these cases are gained from a close study of the personality, and the mode of development of the psychosis.

The author believes that Kraepelin overvalued catatonic manifestations as evidence of a deteriorating psychosis, and that many such cases have served to swell unduly the dementia precox group.

CLINICAL EXAMINATION OF THE MENTAL STATE OF DEMENTS.

Ballet and Genil-Perrin⁷ have worked out a very practical scheme for the examination of the mental state in cases of dementia. It is essential for comparison of cases that some scheme should be adopted and regularly utilized, and the one here elaborated in detail appears very applicable to the task in hand. The authors analyze five different mental functions in their patients *viz.*, affectivity, attention, memory, association of ideas, general activity. Each of these is in turn subdivided, and suitable tests are devised for the examination of each. The results are expressed in figures, and thereby a graphic representation of the patient's mental condition at any given period is obtained.

DEMENTIA PRECOX AND THE THYMUS.

Ebbell⁸ presents evidence which seems to demonstrate a connection between some primary anomaly or acquired disorder of the thymus and the development of clinical symptoms of the dementia precox type. The pathologic anatomic findings in dementia precox, he continues, seem to be identical with those found in animals after partial destruction or total removal of the thymus. This assumption of thymus insufficiency as the cause of dementia precox harmonizes with

the observation of its hereditary nature and with the influence of acute infectious diseases and the abuse of alcohol. When the dementia precox develops in childhood there may be some congenital deformity of the thymus. Attempts to treat animals and human beings with thymus extract or in substance have given no results. This is but natural, Ebbell remarks, as an artificial chemical mixture or devitalized tissue is unable to do the work of the living thymus. Transplantation of thymus tissue seems the only encouraging prospect, and progress must be sought along this line, although Klose and Vogt have reported disappointing results in two dogs. Scraps of thymus tissue were implanted in the omentum and spleen of two thymectomized dogs, but were all absorbed in time.

THE REFLEXES IN DEMENTIA PRECOX.

Borel,⁹ from an examination of twenty-three cases came to the following conclusions: (1) In two-thirds of the cases the tendon reflexes were exaggerated and the cutaneous reflexes diminished. (2) With the exception of Pilez's sign, which was present in 78%, the oculo-pupillary reflexes were too inconstant to be of any value. (3) In 82% Leri's reflex was negative or asymmetrical. (4) Disturbances of the reflexes in dementia precox do not depend upon the clinical variety of the disease, but occur indifferently in every form of it, and do not appear to be affected by states of depression or of excitement. (5) Similar disturbances of the reflexes do not occur in mania or melancholia. (6) Disturbances of the reflexes in dementia precox seem to harmonize with the probability of the lesions being situated in the higher nerve centres, lesions which have been observed by numerous authors. (7) The presence of Pilez's sign and the absence of Leri's reflex in association with the disturbances of the reflexes mentioned (*vide* 1.) may be of considerable value in the diagnosis of dementia precox.

GENERAL PARALYSIS AND PREGNANCY.

Lavergne¹⁰ gives the histories of seventeen cases, three of which are original, and comes to the following conclusions: (1) Pregnancy is rare in general paralysis. (2) Pregnancy may occur at any stage of general paralysis, and appears to accelerate the course of the disease, and sometimes to aggravate the symptoms. (3) In rare cases there is improvement or disappearance of the symptoms. (4) Delivery is followed sometimes by aggravation of the disease, but usually by a transient remission. (5) Pregnancy as a rule goes on to full term. (6) Labor is very often painless, and is in most cases very rapid. (7) The infant is usually normal. (8) Abortions, premature births, or births of children with syphilitic symptoms or malformations are rare.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY.

WORCESTER DISTRICT MEDICAL SOCIETY.

A regular meeting of the Worcester District Medical Society was held in G. A. R. Hall, Worcester, November 11, 1914, under the Chairmanship of Dr. F. H. CLAPP. The meeting was well attended both by members and invited guests. The paper of the afternoon was read by Dr. WALTER D. BIEBERBACH, the title being

THE STORY OF VENEREAL DISEASES.*

The report of the Committee on Control of Venereal Diseases was then presented by the chairman, Dr. FREDERICK H. BAKER, who said:

Mr. President, Ladies and Gentlemen:

In accordance with instructions from the Society at its last meeting your committee has caused 350 circulars and reply cards to be mailed to the physicians of Worcester and to the physicians in the 46 towns represented in this Medical Society. From the 350 communications we received 143 replies, 107 from the city and 36 from the towns, *i.e.* about 40% replied.

The circular was as follows:

COMMITTEE ON CONTROL OF VENEREAL DISEASES.

October 31, 1914.

DEAR DOCTOR:

Syphilis and Gonorrhea are among the most common and dangerous of communicable diseases. Countless numbers are yearly being infected, innocently and otherwise, resulting in untold physical suffering and vast waste of money, both private and public.

Practically nothing has been done to control these diseases. For this reason, this committee desires to ascertain the prevalence of these diseases in our community, and to make a beginning in an effort to control them. We ask your earnest co-operation in this work.

To show briefly the enormity of this evil the following statistical evidence is given.

* See JOURNAL, page 201.

Syphilis infects about 5-10% of the adult population.
 Syphilis causes about 20% of all insanity.
 Syphilis causes about 10% of epilepsy.
 Syphilis causes many of the idiotic and feeble-minded children.

Syphilis causes most cases of locomotor ataxia, many brain lesions and many spinal cord diseases.

Syphilis causes most early apoplexies and many late ones.

Syphilis causes very many cardio-renal diseases.

Syphilis is to be looked for in many "indefinite ailments."

Syphilis causes much infant mortality and many abortions.

It is the one *great hereditary disease*.

Gonorrhea causes more than 10% of blindness.

Gonorrhea causes a very large percentage of the pelvic operations upon women.

Gonorrhea causes about one-half of all cases of sterility.

Gonorrhea causes much joint disease and other septic conditions.

Practically all prostitutes are infected with one or both of these diseases.

Please fill out the enclosed question card and return before November 8th, 1914. The results of this inquiry will be presented at the next regular meeting of this Society to be held Wednesday, November 11th, 1914, at 4.15 p. m. in G. A. R. Hall, 55 Pearl St., Worcester, to which you, whether a member or not, are cordially invited.

COMMITTEE.

"A tabulation of the answers shows the following:

"Question 1. How many cases of Syphilis in any state do you know of? The total number reported in the City of Worcester was 1508, in the towns 188, making in all about 1700 cases.

"Question 2. How many cases of Gonorrhea in any stage do you know of? In Worcester, 984 and in the towns 256, a total of 1240 cases.

Question 3. Do you favor having the Worcester Board of Health do free Wassermann tests for syphilis and free tests for gonorrhea? In Worcester 93 answered 'Yes', 4 answered 'No', 7 answered 'Yes' conditionally, and 3 passed this question. In the towns 35 answered 'Yes' and 1 'No'.

Question 4. Do you favor having the City Hospital establish a special service for the hospital and out-patient treatment of venereal diseases? In Worcester 81 answered 'Yes', 15 answered 'No', 7 answered 'Yes' conditionally, and 4 made no answer. In the towns all 36 said 'Yes'.

Question 5. Do you favor making syphilis and gonorrhea reportable diseases either by name or number? In Worcester 60 answered 'Yes' without comment, 21 'Yes, by number', 1 'Yes' conditionally, 17 said 'No', 8 made no reply. Thus it is apparent that about 80% in Worcester are in favor of some method of reporting these diseases to the Board of Health. In the towns 14 answered 'Yes' without comment, 14 'Yes, by number', 1 'Yes' conditionally, 5 answered 'No' and 2 were undecided.

"These answers are certainly instructive and indicate clearly that the medical men of this city and county are in favor of attacking this venereal problem. While the figures on the number of cases of syphilis and gonorrhea are not definite,—in fact being far below the actual number, for if 40% of the physicians in Worcester report about 1500 of one and nearly 1000 of the other, the remaining 60%

could doubtless report as many more, not to mention the great number treated by druggists, quacks, and by advertised remedies—enough have been reported to show the great prevalence of venereal disease in this community and to warrant an organized effort for their suppression.

"As to means for the medical control of these diseases it is evident from the answers that about 95% of the physicians responding favor such an aid to the early and definite diagnosis as would be afforded by a laboratory for free Wassermann tests for syphilis and tests for gonorrhea, and that they approve of the work being done by or under the direction of the Board of Health.

"Nearly as many, i.e. about 85%, are in favor of the City Hospital establishing a special service for the care of venereal diseases where those unable to pay for treatment privately might obtain proper care during the communicable stage of the diseases. It has been shown that two or three weeks' vigorous treatment will render an active syphilitic practically innocuous to others, while neglected, as is so often the case, it may remain active for months, endangering many.

"As noted above about 85% favor making the diseases reportable. This would enable the authorities to form a correct estimate of the prevalence and the economic and social influence of the disorders, as well as affording a means whereby the careless or viciously indifferent patient could be controlled.

"The information concerning the great prevalence of venereal diseases in our community furnished us by these question cards moves your committee to strongly recommend the following measures for the beginning of the work of attacking them in this city: (1) That the Board of Health establish a laboratory for the free testing for syphilis and gonorrhea. (This could be done for the present at little expense by effecting an arrangement with City Hospital where Wassermann tests have been done for nearly a year.) (2) That Worcester City Hospital establish a department of venereal diseases for both bed and out-patient treatment, the latter to be open one evening weekly. (3) That syphilis and gonorrhea be made reportable diseases—at present by number, as board of health records are now public property and open to inspection. (4) That the present status of the venereal diseases calls for education both of the medical profession and the adult lay population.

"Respectfully submitted by the Committee.

"CLARA P. FITZGERALD, M.D.

"MICHAEL F. FALLON, M.D.

"HOWARD W. BEAL, M.D.

"KENDALL EMERSON, M.D.

"FREDERICK H. BAKER, M.D."

In the discussion which followed Dr. EDW. H. TROWBRIDGE, chairman of the Worcester board of health said that he could vouch for the readiness of all members of the board to advance any effort to control or limit venereal diseases in Worcester. He thought there might be considerable question as to the best method of attacking them. He also pointed out the need of instructing the young before they came to the age of opportunity, that it is better to prevent than to attack it after it is contracted. He spoke of the neglect of parents to fortify the minds of their boys and girls against these dangers before sending them away to school or college and intimated that it might be a proper function of the school physician to instruct in these matters.

DR. ERNEST V. SCRIBNER, superintendent of the Worcester State Hospital, said that the subject was of special interest to him as syphilis was so large a factor in filling our asylums, jails and almshouses. He believes in taking whatever measures promise mitigation of present conditions. At the State Hospital they have been taking Wassermanns for two years, sending the bloods to Harvard Medical School. For purposes of comparison they have sent bloods from 109 cases simultaneously to the Medical School and to Worcester City Hospital laboratory. Reports from the two places agreed in all save the following:

- 4 doubtful at H. M. S. were positive at C. H.
- 1 negative at H. M. S. was positive at C. H.
- 5 doubtful at H. M. S. were negative at C. H.

He therefore thinks it safe to infer that the work at the local laboratory is as reliable as at the other and in certain instances more accurate, the possibility of deterioration in transportation being less. He feels that the City should provide for free tests and that the Society can do no greater good than to assist the committee in the work.

REV. DR. VINCENT E. TOMLINSON, speaking for the pastors present, said that they appreciated the courtesy of the Society. The two professions have much in common, the physical and moral health of the community being interdependent. The initiative in a movement of this sort should come from the medical profession who are closer to the problems and well informed. He approves of letting in the light and is sure the churches will do what they can to help. He cited a case of an innocent death from one of these diseases.

Mr. Fred L. Willis, Secretary of the Worcester Y. M. C. A., said he was much impressed by the force of the problem. He told of how the Y. M. C. A. tried to meet it by lectures to adults and heart-to-heart talks to boys. The trouble is that boys and girls don't know what they are up against. He believes that they can be taught to control passions and that that is the basis of the control of the diseases, i.e. the upbuilding of moral character. Mr. Wilder, the physical director, has been doing it with thousands of boys. The Y. M. C. A. is ready to help.

Dr. A. W. MARSH also emphasized the educational side of the problem, citing a sad case of an innocent infection from a supposedly cured case. He then offered a motion "That the Committee on the Control of Venereal Diseases confer with Worcester Board of Health and with the trustees of Worcester City Hospital to make arrangements with them, if possible, to carry out the recommendations reported by the committee, and furthermore that the committee be authorized by this Society to begin a campaign of education on this subject among adults."

The motion being seconded was unanimously passed by the Society. The Campaign of Education prescribed by that vote is now being organized after the following plan: To send from our ranks lecturers of authority and recognized conservatism of both sexes to speak before subordinate church organizations, parents' associations, lodges, civic organizations, etc., as we may be able to approach them. While these lectures are studiously to avoid the spectacular, it is our intention fully to expose to those having understanding, the spectre of venereal disease to the end that we may have the intelligent co-operation of the public in our program of medical control and of stimulating the inculcation of sound morality in the rising generation by parents, clergy and teachers.

ERNEST L. HUNT, Secretary.

Book Reviews.

Annual Report of the Surgeon-General of the Public Health Service of the United States for the Fiscal Year 1914. Washington, D. C.: Government Printing Office. 1914.

This report by Dr. Rupert Blue, Surgeon-General of the United States Public Health Service, records the activities of that service for the fiscal year ended June 30, 1914. This is the forty third annual report of the service in the one hundred and sixteenth year of its existence. The principal topics dealt with are administrative organization, scientific research, maritime and domestic quarantine, sanitary reports and statistics, marine hospitals and relief, personnel, publications and needs of the service. Especial emphasis is laid on pollution of the Great Lakes and their tributary rivers as a serious menace to public health. About sixteen million passengers are carried annually in sixteen hundred vessels over these waters, which are used by them for drinking purposes. Dr. Blue believes that this fact has an important part in the maintenance of the relatively high typhoid fever rate of the United States and recommends that all water from the Great Lakes should be purified before being used for drinking. There is also great necessity for rural sanitation in the prophylaxis of typhoid. Attention is also called to the adverse report of the committee on the so-called Friedman treatment of tuberculosis, and to the investigation of Von Ruck's treatment now in progress. Among the needs of the service Dr. Blue notes the desirability of an increase in the number of its officers and of its clerical assistants; of an additional building for the use of the hygienic laboratory; and of appropriations for the collection of morbidity statistics and for the publications of the service. Three appendices contain a financial statement, statistical tables and a statement of surgical operations for the year.

A Manual of Diseases of the Nose, Throat and Ear. By E. B. GLEASON, M.D., LL.D., Professor of Otology in the Medico-Chirurgical College; Aurist to the Medico-Chirurgical Hospital; Surgeon in charge of the Nose, Throat and Ear Department of the Northern Dispensary; formerly one of the Laryngologists of the Philadelphia Hospital. Illustrated. Third edition. Thoroughly revised. Philadelphia and London: W. B. Saunders and Company. 1914.

The second edition of this book was reviewed in the JOURNAL of May 18, 1911. This edition has been in many places revised to correspond with the progress of the last few years. It is not intended to be exhaustive, but to furnish a convenient text-book for students and practitioners. In most subjects it is clear, compact and conservative.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, FEBRUARY 11, 1915.

ACTION OF THE ASSOCIATION OF ANATOMISTS REGARDING COLLEGE WORK IN PREPARATION FOR HUMAN ANATOMY.

At the meeting of the American Association of Anatomists held in Philadelphia in 1913, a committee consisting of Drs. H. McE. Knowler, F. T. Lewis, and W. H. Lewis was appointed "for the purpose of standardizing the courses in biology required in premedical courses and leading to the study of anatomy." The American Society of Zoölogists was requested to co-operate in this matter, and promptly responded by appointing a committee, consisting of Profs. H. B. Ward, G. H. Parker, and C. E. McClung, "to confer with the committee from the American Association of Anatomists on the subject of premedical education." These committees have examined the published statements of courses and the many discussions of this subject, and have sought the opinions of representative members of both societies.

The committees agree that it is of the first im-

portance to urge the selection of only thoroughly trained scientific men as teachers of the preparatory work. Such men can be trusted to insist on real scientific methods, and to select the best material and treatment to give the beginner a practical introduction and basis for further work. Beyond this point, however, the committees were unable to proceed. The Zoölogists suggested that the Anatomists should draw up a statement of what they desire the Zoölogists to do in preparing students for anatomy. After this had been done, the Zoölogists were ready to consider how far it is practicable to meet these needs. Accordingly the committee of the Anatomists presented such a statement to their Association at its recent meeting in St. Louis. It was unanimously adopted, and was referred to the joint committee for further action. The statement is as follows:

At the present time a one year's course in biology is generally required as a preparation for the work of the medical school. This study of biology must serve as a preparation for medical work in physiology, bacteriology and parasitology, as well as anatomy, and it may fairly be questioned whether a single college course is adequate for this purpose. The study of botany alone is obviously insufficient, and the domain of zoölogy is so vast that much care should be exercised in the choice of those phases of the science to be presented to young students. Courses which are primarily experimental and deal with the functions and reactions of animals, although excellent in preparation for the physiological work of the medical school, are not the proper basis for the study of human anatomy. It is the purpose of this report to point out only those features of the college preparation which experience has shown to be desirable, and in fact essential, for the successful study of gross and microscopic anatomy.

No uniform or stereotyped preparatory course is recommended, for it is recognized that every teacher should give special attention to those subjects and groups in which he is particularly interested, and to the knowledge of which he has contributed by his own researches. Success depends in large part upon the ability of the teacher, but the following purposes of instruction should not be forgotten if the preparatory work is to satisfy the requirements of anatomy.

1. Students frequently begin the study of human anatomy with an insufficient knowledge of the lower forms of animal life. The broad

knowledge of the various classes of animals and of invertebrate and lower-vertebrate morphology, which was the inspiration of the great anatomists of the past, is now too often replaced by vague considerations of the method of science and ideals of observation. A return to the study of animals, as objects of interest in themselves, apart from theoretical considerations and possible relations to human society, is therefore recommended. The student should obtain a synoptic knowledge of the animal kingdom, and should be able to classify in a general way and to describe the life histories of the common forms of animals, aquatic and terrestrial, which may be collected in his locality. A beginning in such work may well be made by the student independently, or perhaps in high-school courses, but such fragmentary and elementary studies should be supplemented by a thorough college course. The first-hand familiarity with animals should serve as the basis for all further work.

2. As a result of the knowledge of genera and species which the student should have obtained directly for himself by studying some group of animals or plants, questions of the origin of species and of the relation of the great classes of animals to one another, are inevitably before him as philosophical problems. Collateral reading then becomes as necessary for the biologist as for the man of learning in any other branch of knowledge. Selected works of Lamarck, Darwin, Huxley, Mendel and others, should be freely consulted. This literature, which in its influence upon human thought has far outspread the bounds of biology, should not be neglected by the students of zoölogy, whose particular heritage it is. Since the idea that science cannot be read, and that there is no knowledge in books, is often taught as a cardinal principle, it has come about that students of zoölogy have little knowledge of, or respect for, the writings of the makers of their science.

3. Before beginning the study of human histology, every student may reasonably be expected to be familiar with the use of the microscope and with the simpler methods of preparing specimens for microscopic examination. This technic can be learned in connection with various courses, perhaps the most useful of which is a general study of the cell with a comparative study of the elementary tissues. The maturation of the germ cells and the processes of fertilization and segmentation cannot be properly presented in the medical curriculum, and

these fundamental biologic phenomena should therefore be observed in college courses. The development of the chick, which was studied primarily by physicians to explain the growth of the human embryo, can likewise receive little attention in the medical school. These subjects are all very desirable in themselves, and if studied by laboratory methods, will supply the requisite skill in the use of the microscope.

4. In preparing for human dissection, comparative anatomy should be studied with the same standards of thoroughness which obtain in the dissecting room. The student should learn to dissect rapidly and well, and to record with careful drawings and brief descriptions the forms and relations of the structures which he has disclosed. But such studies are not useful merely for their methods. A knowledge of comparative anatomy, including especially the anatomy of the lower vertebrates, is indispensable for understanding the structure of the human body. For other reasons also, human anatomy must be treated as an advanced study. The State does not provide bodies for dissection in order that untrained students may learn from them those elementary facts which may be understood equally well by dissecting cats or rabbits. "It is absurd," says President Eliot, "to begin with the human body the practice of dissection." And the value of dissection is so great in relation both to medicine and surgery, that an adequate preparation should be required. For the study of anatomy, in the words of Lord Macaulay, "is not a mere question of science; it is not the unprofitable exercise of an ingenious mind; it is a question between health and sickness, between ease and torment, between life and death."

5. Finally, these recommendations may be summarized as a plea for a more thorough study of zoölogy on the part of those planning to enter the medical schools. The zoölogical courses should not be abridged and popularized in order that time may be saved for other pursuits, or that the science may seem more attractive to college youth. Courses in anatomy and physiology which duplicate the work of the medical school, and courses in "medical zoölogy" ought not to be substituted for the strictly zoölogical university courses. The science of zoölogy is of such great service to students of medicine that it deserves a large place in their undergraduate studies. With medical anatomy, it constitutes

'a subject essentially one and indivisible'; and the penalty for its neglect is inadequate preparation for medical practice.

REORGANIZATION OF THE BOSTON BOARD OF HEALTH.

THE proposed reorganization of the Boston Board of Health, after a long period of discussion, was finally effected, in its legislative aspects, at a meeting of the Boston City Council on January 30. The change had been opposed by certain political interests but was advocated by the Mayor, the corporation council and numerous physicians. At various of the preliminary hearings, also, had been read letters approving the reorganization from the Norfolk and Suffolk Districts of the Massachusetts Medical Society, the Boston Milk and Baby Hygiene Association and the Boston Association for the Relief and Control of Tuberculosis.

The reorganization actually effected consists in the replacement of the present health commissioner of three members by a single health commissioner who will control seven administrative departments in place of the nine now in existence. Under him there will probably be two deputy commissioners, each of whom will have charge of one of the departments. These deputies are to be appointed by the health commissioner. The seven divisions are to be denominated as follows: medical, sanitary, food inspection, quarantine, laboratory and child hygiene divisions, and a division representing a consolidation of the clerical divisions, so that vital statistics work will be included. This eliminates the present divisions of communicable diseases, disinfection, dairy inspection, and inspection of milk and vinegar.

This reorganization is based on a principle similar to that underlying the recent reorganization of the Massachusetts State Board of Health, —the principle of administration by a highly paid, responsible expert controlling an efficient system of graduated subordinates. It is needless to say that this reorganization of the municipal health board, like that of the state health board, is a cause of gratification to the medical profession. The older forms of health board organization were adequate in their time, but have become incompatible with modern conditions, which require more highly specialized methods of action.

Boards of health first came into being as committees of safety to meet emergencies when epidemic diseases broke out. By natural evolution, these committees became permanent and developed into our present boards of health. It is quite as unwise to manage the health affairs of a large community by a board of health, as it would be to place the command of an army in the hands of a board of generals.

The Boston Board of Health has had a long and honorable record. The changes now effected in the health organization of the city are not on account of criticism of the work of the board, but because boards of health, as such, are relics of the past and have outgrown their usefulness. Economically, a board of health is wasteful, for there are several salaries to pay instead of one. From the standpoint of efficiency, a board is clumsy and makes for divided authority. Most large cities have long ago established their health organization upon modern lines, headed by a commissioner of health. In this way authority and responsibility are centered in one trained official and business is facilitated. The commissioner of health should be the administrative officer and be held responsible for the execution of the health laws and ordinances. He should have an advisory council, public health council, or board of health; such board or council, however, to have no administrative functions, but to be purely advisory, with semi-legislative and quasi-judicial powers.

With the reorganization of the Boston Health Commission thus accomplished in legislation, it remains that a highly efficient and competent expert should be judiciously selected to fill the important office of health commissioner. This selection should be made purely on the basis of merit without regard to political or other considerations.

PROSTITUTION AND VENEREAL DISEASE.

IN another column of this issue of the JOURNAL, Dr. Walter D. Bieberbach reviews the perennial problem of prostitution, venereal diseases, and their prophylaxis. It might seem that there were little new to be said on this insurmountable question, yet Dr. Bieberbach interestingly recapitulates its history, and stimulative criticizes some of the solutions of it which have been

proposed. Venereal diseases he rightly assumes to be a manifestation of prostitution. For the benefit of humanity their control is earnestly to be desired. Yet any measure must be regarded as purely palliative which does not aim at removal of the cause. Doubtless palliative measures are often temporarily advantageous, but they should not be considered ultimate.

Prostitution, as a phenomenon of modern life, represents a reversion to the primitive physiologic condition of sex promiscuity. Early in its evolutionary experience the human race discovered, unconsciously, that such promiscuity is inconsistent with the higher interests with which it was becoming concerned. It therefore established marriage as a substitute. Under good conditions this substitute is effective; but unfortunately conditions are seldom universally good. As a matter of fact, civilization in its progress provides numerous economic and other deterrents from marriage, particularly among the young, with the natural result that in many cases prostitution recurs to afford satisfaction for the biologic instinct.

The real and ultimate remedy for prostitution and venereal disease is the removal of the causes from which they spring. Of these we have mentioned but one. No single measure of control or prevention is going to solve this archaic problem overnight; but perhaps it may fairly be considered that the civilization which shall succeed in improving the conditions surrounding marriage, and in encouraging and making possible early marriage among the young, instead of discouraging and tempting away from it, will have gone far towards the eradication of prostitution, venereal disease, and all their attendant evils.

MASSACHUSETTS STATE HEALTH DEPARTMENT.

WITH the advice and consent of the advisory council, Dr. Allan J. McLaughlin, Massachusetts State Commissioner of Health, has completed the organization of his administration by the following nominations, which have been approved by the Governor and the Executive Council. These appointments are as follows: Dr. Milton J. Rosenman, pathologist; Dr. Eugene R. Kelly, of Seattle, Wash., director of communicable diseases; I. H. Goodnough, chief engineer, director of the division of sanitary engineering; H. W. Clark,

chemist, director of the division of water and sewerage laboratories; William C. Hanson, director of the division of record and accounts; Hermann C. Lythgoe, director of the division of food and drugs.

From the medical point of view these appointments are cordially to be approved. The appointment of Dr. Rosenau to this position has necessitated his resignation as a member of the recently organized public health council, but it is felt that his services will be of greater importance to the community in the former than in the latter position.

One of the deficiencies which has already appeared in the structure of the act establishing the new department of health is the failure to provide penalties for violation of its regulations. A bill to remedy this defect has been introduced before the General Court providing a maximum fine of \$300 for violation of regulations made by the department. On Feb. 2 this bill was discussed in committee, where it was advocated by Dr. McLaughlin, Dr. Enos H. Bigelow, Dr. Walter P. Bowers and Dr. A. K. Stone, and opposed by the representative of the Massachusetts State Grange. It is obviously desirable that this piece of legislation should be passed.

MISCELLANEOUS MATTERS OF MEDICAL LEGISLATION.

SEVERAL miscellaneous matters of medical legislation are at present pending or have been recently dealt with in national and state legislatures. At Washington, on January 28, Congress defeated a bill to increase, by about \$46,000, certain salary allowances in the United States Public Health Service. It was pointed out in the discussion of this measure that in times of peace this service is even more arduous and dangerous than that of the army and navy medical service, and that its members therefore deserve correlative compensation. Attention was called to the casualties suffered by the officers of the public health service within recent years.

"Five of the officers of this service within recent years have contracted tropical dysentery while in line of duty. In the Revenue Cutter Service an assistant surgeon on board one of the revenue cutters in Alaskan waters was drowned while seeking to afford medical relief to a light-house keeper. One died because he was infected with spotted fever while seeking to bring relief

to the people of Montana. Within a period of five years four officers contracted typhoid fever in line of duty and two of them died from that disease. Eleven officers have contracted tuberculosis in line of duty and three of them died from this disease. Twenty officers have contracted yellow fever in line of duty and six of them died of this disease. It is a hazardous service; more hazardous than the Army or Medical Corps in times of peace, and because of the exposure to which these officers are subjected in cases of epidemic and in treating contagious diseases these men should have the same consideration that corresponding officers should have in the army and in the navy."

Comment was also made on the work of the Public Health Service in studying and dealing with malaria, yellow fever, trachoma, uncinaria-sis and small-pox. In spite of the merits of the bill, however, it was unfortunately defeated, largely through considerations of economy.

Another disappointment in medical legislation was the recent vetoing by Secretary Bryan of a plan for the purchase of a modern vessel for the United States Navy to replace the hospital ship *Solace*. It had been announced that the sum of approximately \$2,000,000 was available for the purchase and equipment of such a ship. Of the need of a new hospital ship there can be no question since the *Solace* is an antiquated vessel of only 3300 tons. Even in the small Mexican War of last April the United States naval forces suffered from the inadequate hospital facilities. A suitable steamship of the Ward Line had even been selected, and Dr. Theodore W. Richards, U.S.N., detained to superintend her conversion into a hospital ship. The reason alleged by the Secretary of State for inhibiting this undertaking is fear lest other nations might consider that the United States was thereby preparing for war.

Several minor matters of medical legislation have been under consideration before committees of the Massachusetts General Court during the past week. Before the committee on social welfare, Dr. David Snedden, commissioner of education, advocated the establishment of special schools for children with defective eyesight. Another bill provided an appropriation of \$2500 for making an investigation into the care and relief of the blind not now provided for. Chief Justice Bolster of the Boston Municipal Court advocated a bill authorizing the court to secure medical service for its criminal business at a cost of not more than \$6000 annually. The committee favorably reported this bill and the bill au-

thorizing the Massachusetts Commission for the Blind to establish defective eyesight classes and make an investigation with respect to persons with defective eyesight.

Before the committee on public health Dr. Marion C. Burroughs advocated a bill requiring the removal of noxious weeds from the roadsides in Massachusetts twice a year as a preventive of hay fever. The committee voted to report a resolve to have the state department of health investigate the subject and report to the next legislature. The committee reported adversely on a bill to provide better sanitary conditions in public toilet rooms.

MEDICAL NOTES.

NATIONAL RADIUM INSTITUTE.—Report from Washington, D.C., states that on Jan. 27 the sum of 171 milligrams of radium bromide, valued at over \$11,000 was placed by the United States Government in the hands of Dr. Howard E. Kelly, Baltimore, for use at the National Radium Institute. This radium was extracted from the original ore in Colorado by a new and simplified process developed in the laboratory of the Federal Bureau of Mines at Denver.

MEDICAL BEQUEST.—The will of the late Mrs. Eliza McMillan, filed in the probate court at St. Louis, Mo., on Jan. 25, creates a trust fund based on a contingent bequest of over \$1,000,000 for the ultimate establishment of a hospital in connection with Washington University, to be known as the McMillan Eye, Ear, Nose and Throat Hospital. This hospital may be established as a separate department of Washington University, or may be administered under the direction of the medical department of the school. The bequest is contingent upon the death of the testatrix's only son without issue.

INSANITY IN NEW YORK.—The report of the State Hospital Commission of New York submitted last week to the general assembly at Albany, shows that during the year 1914 6,289 new cases were sent as patients to public hospitals for the insane in that state. During the same period 1677 former patients were re-admitted to these institutions. The total number of insane in the State of New York dependent upon state care is now 33,357, and the annual cost of their maintenance is \$6,729,126.

EUROPEAN WAR NOTES.—A piece of correspondence from the Associated Press dated at London on Jan. 3, and published in the *New York Times* on Jan. 31, indicates a serious shortage of physicians in Great Britain:—

"So serious is the impending shortage that the Royal Army Medical Corps is advising medical students who volunteered for hospital service to return to their schools, on the ground that it is their duty to qualify for their degree as soon as possible.

"Previous to the war the National Insurance act had relieved the profession of overcrowding by absorbing a large number of physicians to inspect and look after insured workers. War has since drawn away so many from home practice that civilian doctors are now scarce, overworked, and high-priced.

"Death has been busy among the Medical Corps men at the front no less than among the line officers. As a result, it is now proposed to take the doctors out of the trenches, leaving the first-aid work to the ordinary Hospital Corps men. The wounded may then be taken to the rear for further treatment."

On Feb. 5 the total of the New York Belgian relief fund amounted to \$896,670.79; the New York Red Cross fund to \$450,689.26; the American Ambulance Hospital fund to \$322,257.85; the Prince of Wales relief fund to \$107,846.63; the Committee of Mercy fund to \$100,746.91; the French relief fund to \$57,522.34; and the American Polish relief fund to \$18,741.52.

On Feb. 6 the total of the New England Belgian relief fund amounted to \$193,399.96; the Massachusetts Red Cross fund to \$108,573.42; the Boston branch of the American Ambulance Hospital fund to \$52,976.45; the Boston Jewish relief fund to \$32,011.92; the American St. George fund to \$19,892.86; the Boston Polish relief fund to \$17,657.38; and the Lithuanian national relief fund to \$10,184.24.

EPIZOOTIC OF FOOT AND MOUTH DISEASE.—On Jan. 26 the sum of \$2,500,000 became available, through President Wilson's signature of an urgent deficiency appropriation bill, to reimburse farmers for the loss of their cattle slaughtered by Government orders during the recent epidemic of foot and mouth disease. In Illinois the sum of \$600,000 will be paid for 36,758 animals killed. The total number killed in Pennsylvania was 17,896 and in Ohio 10,111. The total number killed in all states up to Jan. 1 was 101,111, including 46,268 cattle and 47,735 swine. The total cost of the epizootic to the Government thus far has been \$2,129,138.

On Jan. 27 a few new cases of the disease were found in the Union Stock Yards at Chicago, which have been again disinfected. By a new Federal ordinance effective on Feb. 1, no liable live stock susceptible to foot and mouth disease may be shipped from points within any of the quarantine area to points in a free area. This order affects territory in Delaware, Illinois, Indiana, Maryland, Michigan, Montana, New York, Pennsylvania, Virginia and Wisconsin. On Feb. 1 also four counties in Kansas,—Butler, Cowley, Sedgwick and Sumner,—were quarantined against foot and mouth disease by the

United States Department of Agriculture on account of infection brought by cattle from Wisconsin. On Feb. 2 the quarantine in Maine and Vermont was virtually raised by an order permitting cattle from these states to be brought to Massachusetts for immediate slaughter at establishments under federal inspection. On Feb. 3 two new cases of the disease were discovered at Springfield, Mass.

BOSTON AND NEW ENGLAND.

SOCIAL HYGIENE.—On Jan. 29 Dr. Hugh Cabot spoke at the January meeting of the Longfellow Home and School Association in Roslindale, Mass., on "Social Hygiene as the Result of an Educated Public Opinion."

FIRE AT TEWKSBURY HOSPITAL.—On Jan. 30 a fire in one of the storage buildings of the State Infirmary at Tewksbury, Mass., destroyed property to the value of \$2000 and necessitated the removal of three hundred patients to other quarters.

EPIZOOTIC OF HOG CHOLERA.—Report from North Grafton, Mass., on Jan. 31, states that an outbreak of hog cholera has occurred in that town, and 88 infected pigs have been slaughtered.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH.—At the recent annual meeting of the Massachusetts Association of Boards of Health held in Boston, addresses were made by Dr. Lewis Chargin of the New York Department of Health, Dr. F. H. Baker of the Worcester Board of Health and Mr. Michael M. Davis, Superintendent of the Boston Dispensary. The following officers were elected for the ensuing year:—

Prof. Milton J. Rosenau, Harvard Medical School, president; Prof. George C. Whipple, Harvard University, first vice-president; Dr. A. L. Jones, North Adams, second vice-president; Dr. F. H. Slack, secretary; Dr. F. G. Curtis, Newton, treasurer. New members of the executive committee: Dr. A. S. McKnight, Dr. F. X. Mahoney, Dr. F. H. Thompson, R. L. Newcomb, and Dr. F. G. Wheatley.

TRANSFER OF BOSTON QUARANTINE STATION.—At the organization meeting of the new city council of Boston on Feb. 1, Mayor Curley reintroduced the proposed ordinance for transferring the Boston Quarantine Station from local to federal control. On Feb. 3 it was stated that the Committee of the Chamber of Commerce has voted to reverse its previous decision and to approve the transfer.

NOTIFIABLE DISEASES IN MASSACHUSETTS.—On Dec. 15, 1914, the following diseases were declared by the State Department of Health to be *Dangerous to the Public Health* and so report-

able by law. Householders and physicians must now give immediate notice to the local board of health of all cases of:—

Actinomycosis.	Leprosy.
Anterior poliomyelitis.	Malaria.
Anthrax.	Measles.
Asiatic cholera.	Mumps.
Cerebro-spinal meningitis.	Pellagra.
Chickenpox.	Plague.
Diphtheria.	Rabies.
Dog-bite (requiring anti-rabic treatment).	Scarlet fever.
Dysentery:	Septic sore throat.
a. Amebic.	Smallpox.
b. Bacillary.	Tetanus.
German measles.	Trichinosis.
Glanders.	Tuberculosis (all forms).
Hookworm disease.	Typhoid fever.
Infectious diseases of the eye:	Typhus fever.
a. Ophthalmia neonatorum.	Whooping cough.
b. Suppurative conjunctivitis.	Yellow fever.
c. Trachoma.	

Attention is called to the fact that in accordance with the provisions of Chapter 670 of the Acts of 1913, notice of cases of any disease declared by the State Department of Health to be dangerous to the public health shall be given in such manner as the State Department of Health may deem advisable. On Dec. 15 it was voted that such notice shall be given by physicians on postal cards supplied to physicians by the local board of health with the complete list of such diseases printed thereon for their information.

HOSPITAL BEQUESTS.—The will of the late Mrs. Joel Goldthwait, who died in Boston recently, contains a bequest of \$50,000 to the Robert Bent Brigham Hospital for Incurables, to constitute a fund to be known as the Joel and Ellen Goldthwait research fund, the income to be used for investigation to increase the knowledge of chronic diseases. Additions of \$10,000 have already been made to this fund. The will also contains bequests of \$1000 each to the Sharon Sanatorium, the Children's Island Sanatorium at Marblehead, and the Noble Hospital at Westfield, Mass.

BALDWINVILLE HOSPITAL COTTAGES.—The recently published thirty-second annual report of the corporation of the Baldwinville (Mass.) Hospital Cottages records the work of that institution for the past year. There has been an average of 105 patients.

"Thirty-one patients were dismissed during the year—twenty-one boys and ten girls. Seven recovered or the disease was arrested; fifteen were much improved; seven showed slight improvement; only one went away in the same state of health as when he entered, and one died. The entire number of cases treated within the year was 134. The Boston committee, Miss Edith H. Sears, chairman, has received funds for the support of eight beds for the entire year and one

for nine months. The Woman's Board contributed \$1699.78 toward the schools, free beds and general expenses, which included new boiler-room and additional water-supply equipment."

RING SANATORIUM.—The recently published tenth annual report of the Arlington (Mass.) Health Resort records the work of this institution and of the thirty-fifth year of the Ring Sanatorium during the past year. During the year ended June 1, 1914, 171 patients were under treatment and five pupils were graduated from the Training School.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Feb. 2, 1915: Diphtheria, 52, of which 1 was non-resident; scarlatina, 56, of which 2 were non-resident; typhoid fever, 4; measles, 77; tuberculosis, 40, of which 1 was non-resident. The death-rate of the reported deaths for the week was 15.99.

1. Holt and Babbitt's interesting analysis brings out the following points of practical interest in 10,000 cases: The deaths in the hospital during the first 14 days were 3% of the living births. For half this number prematurity was responsible; 48% of the total deaths and 66% of those due to prematurity occurred on the first day. Congenital weakness and atelectasis together made up 58% of the total deaths. The mortality from conditions intimately connected with delivery—accidents of labor, hemorrhage, sepsis and asphyxia—together made up but 20% of the deaths of the first 14 days. Malformations and congenital diseases other than syphilis caused 4% and syphilis 4%. The only important disease developing after birth was pneumonia. Stillbirths must be reckoned as one of the large problems in infant mortality; they are one and a half times as many as the deaths from all causes during the first two weeks. Except for the larger rôle played by syphilis, the causes of stillbirths differ in no way from those which produce death during the first days of life. The number of deaths from congenital weakness can be reduced only by care of the mother during her pregnancy. The number of stillbirths and deaths from causes connected with parturition can be largely reduced by good obstetrics.

2. Coughlin finds that 4.9% of all cases of sarcoma of the tongue are congenital. Of the non-congenital, 3.2% were found in children under one year of age. No cases are reported between the ages of four and fourteen years; 11.7% occur between 10 and 20 years or 19.6% occur in patients under 20 years. The disease is hence not more common in the earlier years of life. The largest number comes in the fourth decade or 27.4%. Males predominate, the disease occurring nearly twice as frequently in males as in females. In at last 16% a history of previous injury was obtained and may be a causative factor. The right side and near the base seems to be the most common situation. The round cell type predominates. The article is a good one.

5. These authors find that the hemorrhage following nasal and throat operations is much reduced, especially in operations on the turbinates, by the hypodermic administration of pituitary extract, which materially reduces the coagulation time of blood. Blood pressure was increased in 61% and decreased in 39% of cases.

8. Peckham shows how a simple traction apparatus will often accomplish perfect reduction of a fracture of both bones of the lower leg without open operation. The method is certainly worthy of trial before operation is considered.

16. Curtis believes that subcutaneous injection of whole human blood in repeated doses in practically all hemorrhagic conditions is equally as valuable as transfusion. [E. H. R.]

19. STIMSON, G. W. *Breakage and Removal of Eustachian Applicator.*
20. NELSON, A. *Prostatic Abscess Opened Through the Cysto-Urethroscope.*

1. Rubinow's article is very well stated, and of much interest to the profession. It should be read.

4. Newell's article is also one of much value. It shows the great value of repeated blood pressure examinations during pregnancy. Cases with a constant pressure of from 100 to 130, who did not show albumen, with one exception, had normal pregnancies and developed no signs of toxemia. Cases with pressure lower than 100 are apt to be in poor general condi-

on and show shock at the time of labor. Those with pressure over 130 and in whom albumen appears are very liable to develop signs of toxemia.

11. Beebe makes a careful review of the whole subject of his antiserum for the treatment of hyperpyroidism, giving his theories as to its action, its reparation, and type of cases in which it is most suitable and the results. He considers 50% of 3000 patients cured in so far as they are able to meet the ordinary demands of life, 30% were somewhat benefited and 20% remained unrelieved.

13. Weil advocates the use of sodium citrate in proportions of 1 c.c. of a 10% solution in water to each 10 c.c. of blood, in transfusion. This avoids immediate clotting, and transference of blood can be made readily with a syringe in the hands of anyone without especial experience. [E. H. R.]

*FLEXNER, S., NOGUCHI, II., AND AMOSS, H. L. *Concerning Survival and Virulence of the Microorganism Cultivated from Poliomyelitic Tissues.*

3. Petroff describes a simple and rapid method for the cultivation of tubercle bacilli from the sputum and feces. The method depends largely upon addition of gentian violet to an egg-beef-julice medium. Posi-

tive cultures were uniformly obtained from all specimens of sputum, from all stages of tuberculosis. Positive cultures were occasionally obtained from sputum which had previously been positive for tubercle bacilli but were negative at that time by direct microscopic examination. The results from the feces were not so constant.

4. Auer discusses in an exhaustive fashion the intraspinal injection of sera and its dangers. He believes that the dangerous alterations of respiration and blood pressure are apparently largely due to increased intraspinal pressure rather than to the preservative drugs. He suggests that ether, which could be removed before injection, might well be a better preservative than chloroform or trichlorol. As general precautions he advises that when intraspinal injections are given in human beings the operator should be prepared to withdraw part of the injected fluid and to administer artificial respiration.

6. Flexner, Noguchi and Amoss found that the minute microorganism cultivated from poliomyelitic tissues survives and maintains its pathogenicity in cultures for more than one year. [R. I. L.]

Correspondence.

PERSONAL AND SURGICAL CLEANLINESS.

Boston, January 21, 1915.

"Beauty is Truth, Truth Beauty, that is all
Ye know on earth and all ye need to know."

"It hardly seems necessary to impress upon intelligent people the importance of personal cleanliness, for with such it is a matter almost of instinct. There is in every civilized community an all too large proportion of individuals who never bathe and who regard a bath as a positive danger to health, as every physician who has had experience as a hospital interne or in practise among the ignorant poor can abundantly testify." (Harrington and Richardson, "Hygiene.")

Mr. Editor: Is personal hygiene the propaganda of sentimentalists or is there any scientific basis for keeping clean?

Almost the first and certainly one of the most striking arguments ever laid down for personal cleanliness is that of our own Dr. Oliver Wendell Holmes in his original contribution to the subject of puerperal fever.

The discovery of the germ theory of disease followed by antiseptics and then asepsis revolutionized medicine in the prevention through personal cleanliness of all types of sepsis. Is asepsis a matter for the operating room only? Is it not a valuable asset to the individual whose environment brings him continuously in contact with all kinds of disease? What is asepsis but the epitome of the doctrine of personal cleanliness? Hospital gangrene, infected wounds, and general infections originating therefrom, may be practically eliminated by rigid attention to one's personal cleanliness.

In the realm of every-day life it is an accepted fact that persons taking daily cold baths enjoy a virtual immunity from common colds. Is not this a strong argument for the use of water, especially when we consider the whole train of sequelae, in sinuses, ears, and respiratory tract which may follow a cold?

For the infant, bathing is more generally regarded as an essential factor to health. It is only the adult on whom a modicum of filth as a covering is considered innocuous. Pfaunder and Schlossman in "Diseases of Children" state categorically "The proper care of the skin is absolutely essential to healthy development. . . . Daily bathing is necessary from birth."

Dr. White in his little book on "The Care of the Skin" emphasizes this still more strongly as the most important factor in preventing eczema in infants.

Hoffman states that "bathing is more nearly a panacea for human ills than any other known agent." Assuredly in the realm of skin diseases an ounce of prevention in the form of soap and water is worth a pound of cure. Impetigo, many forms of eczema, pediculosis, scabies, ringworm, tinea versicolor, syphilis, seborrhea and a host of others including acne and furunculosis are in the vast majority of cases prevented by rigid habits of cleanliness from birth. Dr. White again emphasizes the importance of cleanliness in writing of furunculosis: "Sterilize the skin by frequent warm baths in which plenty of soap is used, . . . cleaning the skin is all important in stout people. . . . Take particular care where the hair grows; wear clean clothes."

In the matter of baldness, next to the influence of heredity Dr. White calls attention to the need of frequent and thorough washing of the head from birth, rigid asepsis in the use of toilet articles, advocating strongly the carrying of one's own brush and comb to the barber's and making him observe personal cleanliness. The incidence of baldness in men may be largely due to infections conveyed from person to person through the medium of barbers.

Thompson, in his recent authoritative work on occupational diseases distributes printed slips to workmen such as the following:

"A full hot bath should be taken twice every week, soaking and soaping the body well. If the occupation has involved exposure to irritant dusts, vapors or fumes, the body should be sponged with warm water and well rubbed every night before going to bed. . . . Workers who are exposed to the fumes of molten metals should be afforded facilities for daily shower baths before going to their homes."

For the prevention of lead poisoning: Personal cleanliness must be had. Wash with warm water and soap daily—always before eating—and take at least one full hot bath a week."

Some of the other diseases largely controlled by personal hygiene are glanders, poisoning with antimony, arsenic, brass, chromium, copper, lead, mercury, platinum, silver, carbon, bisulphid, phosphorus, carbolic acid, hydrofluoric acid, picric acid, chinin, metol, nitroglycerine, paraffin, phenolhydrazin and tar.

Care of the teeth is nothing more than bodily cleanliness and our present growing knowledge of the dangers of general infection from dental foci adds one more argument to the importance of personal hygiene in preventive medicine.

If there is any rationality in promoting the activity of the skin as an excretory organ in such diseases as chronic nephritis, there must be some rationality in keeping one's skin clean even with healthy kidneys.

It is now known that "contact" infection plays a very much greater rôle than "air-borne" infection in spreading the bacterial diseases. We should, therefore, expect that personal hygiene would play an important part in prevention. On this point Rosenau writes: "Personal prophylaxis in tuberculosis consists in avoiding infection, obeying all the dictates of personal hygiene and living a clean normal and temperate life." He speaks of leprosy in much the same terms. Of cholera, he writes: "Personal prophylaxis first of all requires scrupulous cleanliness of the person and surroundings." Of dysentery: "There are two essentials, scrupulous cleanliness and boiling of water and cooking of all food." Of hookworm: "After all, prevention of hookworm disease is a question of decency and cleanliness." And so the list grows from year to year.

Sometimes individuals living in educated communities minimize the importance of personal hygiene because they are themselves healthy and yet omit many of the rules of hygiene from their lives. They do not remain well because dirt is healthy but because other

individuals in their environment protect them through cleanliness from many of the transmissible diseases.

Sanitarians who used to say that thorough safe guarding of water supplies and food supplies was the most important factor in guarding the public health now say that education of the individual is the essential factor. Educate the individual to the idea of personal and public hygiene and the community diseases will be starved out. Overcrowding, dirt in tenements, poor food, are flagrant causes of diseases. Educate the individual to the ideals of personal cleanliness and our slums would vanish, for no person who is himself scrupulously clean will live or work in a filthy environment. The character of a person is known by the condition in which he keeps his house, his office or his workshop. Cleanliness is truly next to Godliness.

Very truly yours,

HUGH P. GREELEY, M.D.

THE EMPLOYMENT OF NURSES SUSPENDED FROM TRAINING SCHOOLS.

MASSACHUSETTS GENERAL HOSPITAL,

BOSTON, February 1, 1915.

Mr. Editor: May I call the attention of your readers to a bad condition that might be remedied with their assistance?

A few months ago a young woman called on me to ask to be reinstated in the training school, having left it ten years earlier. She wished to get her diploma so as to qualify for institution work. She said she left the school on account of illness at home and instead of returning to finish her course, had been doing private work successfully ever since. To strengthen her position she said she could give me references from our best known doctors who had employed her, even in their own homes; also that much of the time she had received the usual remuneration of the trained nurse. She said she had to ask the usual rates, otherwise her patients would have known she was not trained and would not have wanted her.

On looking up her record I found that she had been suspended at the end of six months in the hospital, and had never returned. I also found that her statement as to private work was true and that there were prominent doctors ready to endorse her.

Recently another woman who had been dismissed from the school twenty years ago after seven months in the school, called and said she had been private nursing successfully off and on ever since. Another undergraduate has been employed by the city in a graduate's position, no inquiry at the school having been made as to her credentials.

Many private nurses can tell of meeting such impostors on cases and in one instance that I know of the pupil had been dismissed for stealing. The graduate who met her on a case was persuaded not to betray her, and learned a lesson in ethics later, when some jewelry was missing in the home where they were both working on an equal footing.

Schools do not dismiss nurses without good reason, because it involves too much hardship for the hospital, if for no other consideration.

The nurses' uniform is not protected and consequently is no guarantee of graduation. Ought not doctors to know whether the nurses who work for them are really graduates or not? Ought patients to be deceived, and who is to protect them unless the doctor does? Hospitals where nurses should be under constant skilled supervision are the only safe places for partially trained nurses to practise.

If in six months a young woman of ordinary intelligence can learn enough to satisfy the physicians and if her services are worth \$25 per week to the people who employ her, there seems to be no reason why the three year graduate should compete in that field. Personally I heartily approve of the trained attend-

ant, although I should recommend a year's training and practise in elementary nursing methods, before permitting her to practise. I should like to see her registered as an R.A. (Registered Attendant) and do not doubt but that she would meet a long-felt need, but I do feel strongly that our work is too important to permit of a continued indifference to the present slipshod methods of employing nurses.

Correspondence schools and some hospitals are making capital out of the reputation made by and the opportunities open to real trained nurses. Who ultimately suffers most by the indiscriminate flood of pseudo-nurses turned out on the public? The public itself, of course—it is getting poor service and paying dearly for it.

The reputation of trained nurses is being so begrudged that only a few schools can attract the best women, and graduates of the schools that do maintain high standards are shrinking more and more from private duty. The question is being asked, "Why should nurses care for private work?" There are still some physicians and many people who want the most skilled nursing they can get for their patients and these are the people who must help us in improving our nursing schools and in obtaining needed legislation.

Faithfully yours,
SARA E. PARSONS, R.N.

AN EARLY INVESTIGATOR IN ANESTHESIA.

January 27, 1915.

Mr. Editor:

May I importune you to aid me through the columns of your valuable journal to secure some biographical data regarding Dr. E. R. Smilie, of 22 School Street, Boston, who in 1846, two weeks before Dr. Bigelow's epoch-making contribution on "Ether Anesthesia," in the BOSTON MEDICAL AND SURGICAL JOURNAL, published an article on "The Use of the Ethereal Tincture of Opium for the Relief of Pain During Surgical Operations."

Dr. Smilie was later intimately associated with the pioneers who made anesthesia a practical adjunct of surgery, and the undersigned is anxious to secure all possible information regarding his life, personality and work.

Any pertinent communications will be gratefully acknowledged and duly credited in the effort to illuminate the rôle which Dr. Smilie played in the Historical Evolution of Anesthesia.

Respectfully yours,

F. H. McMECHAN,

044 Wesley Ave., Editor: Quarterly Supplement of
Cincinnati, Ohio. *Anesthesia and Analgesia.*

[NOTE: The article by Dr. Smilie was a letter published in the issue of the JOURNAL for Oct. 28, 1846, (Vol. xxxv, p. 263), and that by Dr. Bigelow in the issue for Nov. 18, 1846, (Vol. xxxv, p. 309). The latter has reference to Morton's first public administration of ether at the Massachusetts General Hospital on Oct. 16, 1846. Dr. Smilie's letter is of such interest, from its close connection with Morton's discovery, that we take pleasure in reproducing it in full.]

UNSENSIBILITY PRODUCED BY THE INHALATION OF THE VAPOR OF THE ETHEREAL SOLUTION OF OPIUM.

To the Editors of the Boston Medical and Surgical Journal.

Sirs: As it is frequently found desirable to produce insensibility in persons requiring painful operations, I have made use of the ethereal solution of opium for that purpose, with excellent success, when reduced to vapor by gentle heat, varying the amount inhaled according to the length of time required for the operation; and from the entire absence of symptoms induced by pain, and those which usually result from

the excessive use of opium, I have thought the method of preparation and exhibition invaluable in removing the dread in severe, and the minor operations of surgery. As a medicinal agent in cases of pulmonary irritation, it is beyond doubt the best vehicle for the introduction of opium into the system, and will, when fairly tested by experiment, I have no doubt, prove eminently successful, in a great variety of complaints requiring sedative treatment, from the power that it possesses for the instantaneous development of its effects, through the diffusible agency of the solution. The course which I have usually pursued in preparing the combination for inhalation, is by the introduction of the quantity of the cold ethereal solution of opium required by the urgency of the symptoms, into a glass retort, and by causing a slow evaporation with moderate heat, the patient being permitted to breathe the gaseous vapor from an elastic tube affixed to the mouth of the retort. The judgment of the physician is to be exercised with regard to the quantity inspired, which must be regulated according to the character of the disease and the duration of the required operation.

Yours, etc.,

E. R. SMILIE.

22 School Street, Boston.

Miscellany.

PHILIPPINE CIVIL-SERVICE EXAMINATIONS.

MEDICAL INSPECTOR AND SURGEON (MALE), \$3,000.—

The United States Civil Service Commission announces an open competitive examination for medical inspector and surgeon, for men only. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Philippine Service, at a salary of \$3,000 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The duties of the position will be to take charge of the health station at Manila or in the Provinces, as the Philippine Director of Health may require, and to attend to such surgical work as may be assigned in the Philippine General Hospital, probably the best institution of its kind in the Eastern Hemisphere, with 350 beds and an equipment comparing favorably with that of any hospital in the world. The new conditions, and the as yet undescribed diseases, that are constantly encountered furnish a wide field to one interested in his profession. As a further aid to his work the Bureau of Science, which is on the hospital grounds, has one of the largest and most favorably known research laboratories in existence.

SPECIALIST IN MENTAL AND NERVOUS DISEASES (MALE), \$3,500.—The United States Civil Service Commission announces an open competitive examination for specialist in mental and nervous diseases, for men only. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Philippine Service at a salary of \$3,500 a year, with subsistence, quarters, and laundry, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The duties of this position will be to organize and administer an insane asylum to be located on an estate of 600 acres, to exercise general supervision over the farm work, and to train a staff of nurses and attendants for this special work.

BACTERIOLOGIST AND PATHOLOGIST (MALE), \$2,000 to \$2,500.—The United States Civil Service Commission announces an open competitive examination for bacteriologist and pathologist for men only. From the register of eligibles resulting from this examination

certification will be made to fill vacancies in this position, Bureau of Science, Manila, P. I., at salaries ranging from \$2,000 to \$2,500 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The duties of this position will be to carry on research work in the laboratories of the Bureau of Science, combined with the regular routine bacteriological and pathological work.

These examinations are open to all men who are citizens of the United States and who meet the requirements.

Persons who meet the requirements and desire this examination should at once apply for Forms B. I. A 2 and 2095, stating the title of the examination for which the forms are desired, to the United States Civil Service Commission, Washington, D. C.; the secretary of the United States Civil Service Board, post office, Boston, Mass.; Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; Seattle, Wash.; San Francisco, Cal.; customhouse, New York, N.Y.; New Orleans, La.; Honolulu, Hawaii; or customhouse, St. Louis, Mo.; or to the chairman of the Porto Rican Civil Service Commission, San Juan, P. R. No application will be accepted unless properly executed, including the medical certificate, and filed with the Commission at Washington, with the material required, prior to the hour of closing business on March 2, 1915. The exact title of the examination as given at the head of this announcement should be stated in the application form.

BELGIAN PHYSICIANS' RELIEF FUND.

WEEKLY REPORT OF THE EXECUTIVE COMMITTEE.

The committee of American physicians for the aid of the Belgian profession is constantly receiving heart-rending reports regarding the distress of our Belgian colleagues and their families. Their plight is indeed a sad one. The urgency of the situation resembles that of a great conflagration. Promptness of action doubles and trebles its value. February will be a hard month in Belgium, with great suffering from severe weather added to their other trials.

Our English colleagues are fully awake to the situation. Though their number is small compared to that of America, they have contributed several thousand pounds to this cause. Arrangements have been perfected by which contributions are being promptly converted into supplies with every assurance that they will reach our destitute colleagues. Two hundred boxes of food have been purchased during the week ending January 30.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING JANUARY 30.

ERRATUM.

Owing to accidental dropping out of a slug, which was not detected in reading the page proof, the title of an article by Dr. James M. Jackson, and Dr. W. D. Smith, was incompletely printed in the issue of the JOURNAL of January 28. The title should have read: "Blood Picture Simulating Lymphatic Leukemia in Acute Infection after Removal of the Spleen." We exceedingly regret the occurrence of this accident and express our sincere apologies to the authors.

SOCIETY NOTICE.

THE HARVEY SOCIETY.—The eighth lecture of the series will be given at the New York Academy of Medicine, 17 West 43d Street, on Saturday evening, February 13, at 8.30 P.M., by Prof. John A. Fordyce, of Columbia University. Subject: "Some Problems in the Pathology of Syphilis."

RECENT DEATHS.

JOHN CUNNINGHAM CLYDE, D.D., M.D., who died on January 28 at Easton, Pa., was born in White Deer Valley, Pa., on October 22, 1841. After graduating from Lafayette College he served throughout the Civil War as a provost marshal under General Grant in Kentucky. He subsequently studied both medicine and theology and was finally ordained to the Presbyterian ministry. He was a member of various historic and scientific societies and the author of several religious and medical works.

DR. PATRICK T. McDONOUGH, who died on February 4 at Woburn, Mass., was born on January 16, 1881. After engaging for a time in the practise of optometry he was appointed inspector of food and drugs for the Massachusetts State Board of Health. He was unmarried.

DR. SAMUEL WOOD LANGMAID, M.D., died at his home in Brookline, Mass., February 3, 1915, aged 77 years. He was born in Boston June 26, 1837, was educated in the Roxbury Latin School and in Harvard College, graduating in the class of 1859, and was a graduate of the Harvard Medical School in 1864. He was a member of the American Laryngological Society and had held many appointments in the hospital of Boston as laryngologist. He was much interested in music and was an accomplished tenor singer himself, while he cared for the throat troubles of many of the musical profession. He is survived by his widow and two daughters.

THE TREATMENT OF DIABETES.*

BY FREDERICK M. ALLEN, M.D., NEW YORK.

[From the Hospital of the Rockefeller Institute for Medical Research, New York.]

It is customary to emphasize the importance of the subject of the treatment of diabetes by calling attention to the increase of diabetes among civilized peoples. Magnus-Levy¹ gives German hospital statistics showing that in thirty years the total number of patients increased 3.3 times, and the number of diabetic patients increased 19 times. Not merely the number of cases, but also the number of deaths has increased. The statistics for the registration area of the United States show, from 1901 to 1905, an annual average of 3772 deaths from diabetes, and a steady subsequent increase, so that in 1912 the deaths from diabetes were 9045. Authorities are practically unanimous in the opinion that improved diagnosis is not enough to account for this increase, that is, the increase is real and not merely apparent. Moreover, as Magnus-Levy points out, mortality figures fail to show the true incidence of diabetes. The majority of diabetics are elderly persons, and these often die of some cause other than the diabetes itself. Even among younger persons many deaths are recorded under tuberculosis and other infections, when the important predisposing cause was diabetes. Accordingly, the situation is that present prophylactic methods have not prevented an increased incidence of diabetes, and present thera-

peutic methods have not prevented an increased death-rate.

Rollo, an English army surgeon, in 1796 inaugurated modern diabetic therapy by limiting patients to animal food. Bouchardat and Cantani restricted the harmful excess of protein, and employed green vegetables. Naunyn has wielded a powerful influence in favor of the restriction of protein, and also occasional fast-days. His life has extended from the pioneer period to the present, and he deserves to be honored as the foremost clinician in the history of diabetes, whose methods and ideas have stood the test of time better than any others. Stadelmann, a pupil of Naunyn, in 1883 founded the theory of acid-poisoning as the cause of diabetic coma, and inaugurated the alkali treatment. Van Noorden in 1903 introduced the so-called "oat-cure." Various workers have elaborated these methods in various details, but essentially they constitute the present treatment of diabetes, and are the only measures that have shown any therapeutic value. No text-book or reliable treatise on diabetes claims that every case can be checked. On the contrary, all authorities describe a considerable class of cases that are past hope, and all agree in giving such patients carbohydrate for the sake of diminishing acidosis.

Special mention may be made here of treatments which have involved fasting. Naunyn's use of occasional single fast-days was to clear up a resistant glycosuria, to improve tolerance, and to ward off coma. Van Noorden makes use of the increased tolerance resulting from fast-days or vegetable days as a preparation for his oat-meal treatment. He also now follows Naunyn's plan of one or two fast-days to prevent coma, and he describes the immediate rapid fall of aci-

* Read at a meeting of the Suffolk District Medical Society in connection with the Boston Medical Library, December 2, 1914.

dosis thus produced. In a correct and forcible metaphor, he speaks of these days as "metabolic Sundays." He states that the benefit of these days is such that he can generally make the patient gain weight in the few days immediately following. This custom of forcing the patients to gain weight may prove to be a mistake which he and others make in the treatment of severe diabetes. Another form of using fast-days is the method introduced by Guelpa² of Paris. He believes that diabetes is an auto-intoxication. His treatment is a fast of three days or more, with a bottle of hot Hunyadi-Janos water each day, followed by first a milk, and then a vegetable diet, with occasional repetition of the fasting and purgation. It would be easy to aim ridicule at Guelpa, as those who read his original work will perceive. But it is better to emphasize the serious fact that Guelpa has used a rigorous fasting treatment for diabetes, and has demonstrated real benefit from it in some cases. On the other hand, his theories are grotesque, his excessive purging is an unnecessary inconvenience, and his milk and vegetable diet precludes success in any but mild cases. A search of his list of so-called cures shows that there is not a severe case among them. The rather startling character of Guelpa's treatment, and his exaggerated claims and active propaganda for it, have roused some interest among physicians and laymen in various parts of the world. Some quacks and nostrum-makers have taken their cue from him, and recommend fasting and purgation. Authorities on diabetes have ignored his treatment, because it is so far inferior to the ordinary rational methods. But, though the other features are erroneous, the benefit of the fasting deserves to be recognized.

There is considerable confusion regarding diabetes and glycosuria, and some physicians distinguish alimentary glycosuria, nervous glycosuria, gouty, hepatic, or other forms of glycosuria, as entities distinct from diabetes. Renal glycosuria is perhaps a rare genuine condition. There is no better rule than that made by Joslin³: "I consider any patient to have diabetes mellitus and treat him as such, who has sugar in the urine demonstrable by any of the common tests. This is a broad definition, but is safer for the patient than the use of the term glycosuria, which begets indifference." There are a few patients who, because of advanced age or other special reasons, need little or no treatment for their diabetes, and the main object is to keep them comfortable. My remarks throughout this paper are meant to apply only to that great majority of diabetics who are unquestionably in need of treatment.

It is impossible here to go into details of the theoretical and experimental side of diabetes, which I have reviewed elsewhere.⁴ To assist clearness, one statement may be made concerning the doctrines of the Vienna school, which has upheld especially two interrelated theories. One is that diabetes is nothing but an increased production of sugar, without loss of the power to

utilize sugar. The other is the polyglandular or pluriglandular doctrine, which represents diabetes as a loss of balance between antagonistic glands; in particular, the chromaffin system, as a stimulator of sugar production is supposed to be resisted by the pancreas, as an inhibitor of sugar production. The one statement to make concerning both these doctrines is that they have never been supported by facts; and it would not be necessary to mention them here except for the over-zealous manner in which they have been promulgated among the medical profession. Certainly the great mass of evidence and the great majority of investigators favor the view that in diabetes there is a loss of power to utilize sugar, not a mere acceleration of sugar formation. Also, the internal function of the pancreas is somehow to make possible the utilization of sugar by the tissues. There is no valid proof in the entire literature to show that the adrenals oppose this function of the pancreas, or that the pancreas inhibits sugar formation or opposes the adrenals in any way. Most of those here are familiar with the work of Cannon, who has shown how states of strong emotion are attended by splanchnic stimulation, adrenalin discharge, and hyperglycemia, and has suggested the explanation that this mechanism provides increased sugar for the muscular activity naturally associated with such emotions. I cannot forbear mentioning how unthinkable such a mechanism would be, if the adrenal stimulation and adrenalin discharge opposed the utilization of the sugar by the tissues. It will conduce to clearness if people will dismiss from their minds those diagrams showing imaginary lines running between pancreas, adrenals, liver, thyroid, etc.

The best established and most generally accepted theory is that diabetes results from deficiency of the internal secretion of the pancreas. In a relatively small number of cases there is gross destruction of pancreatic tissue by infection or otherwise, and here early surgical intervention, in the form of drainage of the gall-bladder or other suitable measures, is presumably the most important treatment. In the great majority of cases the gross appearance of the pancreas is normal. Changes in the islands of Langerhans occur in animals with experimental diabetes, and changes in the islands of human patients are being found more frequently as they are sought more carefully. Even after the longest and severest clinical diabetes, changes in the islands may be difficult to discover, and complete destruction of all the islands in the human pancreas must be a great rarity, if it ever occurs. In animals the islet changes are secondary to the diabetes. In human cases it is still unknown to what extent the changes are primary, producing the diabetes, or to what extent they may be secondary, produced by the diabetes. It seems that a considerable functional factor is generally present; that we are never dealing entirely with destruction of tissue which cannot be replaced, but always with a certain element of disturbed

function, which can be broken down by overstrain or strengthened by rest. On the other hand, a full return to normal function is practically never obtainable.

Macleod,⁵ in the opening of his book, gives a simple objective description of diabetes. He states how it appears at first as a weakened function of carbohydrate metabolism, next there is a weakened function of protein metabolism, and then in the severe cases an imperfect metabolism of fat. If we follow this plain, simple idea, it guides us to a rational therapy. Diabetes is commonly looked upon as a progressive, fatal disease. Of course in one sense it is a disease. But in another sense, it may be beneficial to implant the idea in both physicians and patients that diabetes is *not a disease*. There is no evidence that it is an infection, or an auto-intoxication, or anything else of that order. So far as I am aware, an inherent downward tendency has never yet been demonstrated in typical cases. For practical purposes we may well keep to the simple idea mentioned above, that diabetes is merely the weakness of a bodily function, namely the function of assimilating certain foods. It may be compared with indigestion. A weak stomach* may never become a strong stomach, but there is no cause for death unless the patient abuses the weak organ. The possibility and perhaps the probability exists that a weak pancreas is something analogous. Every person has his weak point, and ultimately breaks down at some one point, rather than everywhere simultaneously. If diabetes is a weakness of the pancreatic function, we can understand why the breakdown is most frequent in elderly persons, but generally most serious in young persons. This idea began with Naunyn. If a person overtaxes a weak stomach, the resulting distress punishes the error and forces him to desist. If he overtaxes a weak pancreas, nothing but intelligence can show him what is wrong. If there were no prompt reflex mechanism to prevent and punish overtaxing the digestive function, doubtless the death-rate from indigestion would be fully as high as the death-rate from diabetes now is, and indigestion might appear as a progressive fatal disease, for which all sorts of explanations and all sorts of remedies would be offered. Many dyspeptic sits at table and longs for pleasant-tasting food, but dares not eat it because of the immediate penalty. Many a diabetic sits at table and longs for certain food, and perhaps eats it, even though he knows better. This is merely an illustration that the lower nerve centers are often more effective in controlling conduct than the higher centers. But if the conception is correct, of diabetes as the simple weakness of a bodily function without inherent downward tendency, then if the patient is obedient he may be kept from going down-hill simply by preventing him from overtaxing his weakened function. The weak pancreas may never become a

strong pancreas. The patient may never be entirely normal again. But if our idea is fully correct, this precaution may save life.

The form of treatment embodying this idea was first worked out on animals, and has been described briefly elsewhere.⁶ When about nine-tenths of a dog's pancreas is removed, the resulting condition may appear as a progressive fatal disease. But obviously we have produced not a disease, but merely the weakness of a certain function. If we try to keep the dog fat, and satisfy his large appetite, he goes steadily down-hill for several months, and dies in extreme cachexia. But we can stop glycosuria by fasting, and can then place the animal on a low diet which will support life without producing glycosuria. Such an animal is thin, but strong and lively, with no cachexia and no sign of downward tendency. The treatment for patients is similar. The first step is to fast till glycosuria ceases, and then for twenty-four or forty-eight hours longer. At the same time, the ketonuria falls steeply. It quickly approximates what a normal individual would show under similar conditions, and the aim is to keep it constantly down to this level. Plain fasting suffices for the purpose; but since alcohol is a food which does not produce glycosuria and is said to diminish ketonuria,⁷ it is generally given during fasting, especially if there is danger of coma. Its use or omission in later treatment depends upon individual conditions. Alkalies may be useful for the first few days if coma seems imminent, but are then no longer needed. Continuing the sodium bicarbonate may cause the ferric chloride reaction to remain positive longer than it otherwise would, with no benefit to the patient as far as I have seen.

When the fasting patient has been free from glycosuria for twenty-four to forty-eight hours, the next step is to begin feeding very slowly and cautiously. There need not be a fixed program. It is desirable to individualize the diet to suit the needs of different patients, and various physicians may have personal preferences of their own. The one requirement is that the patient must remain free from both glycosuria and acidosis. Any trace of sugar is the signal for a fast-day, with or without alcohol. The original fast, to clear up the urine in the first place, may be anything from two to ten days, but after that no fast need be longer than one day. The things to be considered in the diet are carbohydrate, protein, fat, and bulk. Frequently the first thing given after the fast is carbohydrate. No distinction is necessary between different forms of starch, but there are advantages in using vegetables, following Joslin's convenient classification on the basis of carbohydrate content.⁸ The first day after fasting, the only food may be 200 grams of vegetables of the five and six per cent. classes. This is increased day by day until a trace of glycosuria appears, which is checked by a fast-day. The purpose of such a program is to learn the carbohydrate tolerance and to clear up the last traces of acidosis. After this carbohydrate

* This term is of course meant only in the usual colloquial sense, to signify the digestive function.

period, or sometimes in place of it, protein is given. On the first day perhaps one or two eggs are given, and nothing else. More protein, generally as eggs and meat, is added day by day, until the patient either shows glycosuria or reaches a safe protein ration. The purpose here is to learn the protein tolerance, and to cover protein loss as quickly as possible. Fat is somewhat less urgently needed, except in very weak and emaciated patients, and it can be added gradually, as conditions seem to indicate. An element of bulk in the diet is necessary to give the comfortable feeling of fullness, and to prevent constipation. This is the great advantage of green vegetables. When they are fed raw, or cooked in steam, or boiled and evaporated so that no water is thrown away, they contain a definite quantity of carbohydrate, besides valuable salts; and this is the only form of carbohydrate that patients thus treated ordinarily receive. Some cases are so severe that even green vegetables cannot be tolerated. A little girl now in the hospital showed glycosuria when she was given nothing but 100 grams of celery and lettuce distributed through the day. Under these conditions the vegetables may be boiled through three waters, throwing away all the water. Nearly all starch is thus removed, and the most severe cases generally take these thrice-cooked vegetables gladly and without glycosuria.

One result of the initial program here described is the loss of weight. This is the thing which physicians have been accustomed to dread most but which, according to present indications, is beneficial in itself. In subsequent treatment, the patient is welcome to gain weight up to a certain point, provided he can do so without glycosuria or acidosis. The attempt to put on weight, according to the time-honored traditions of diabetic treatment, is one of the surest ways of bringing back all the symptoms and sending the patient down-hill. It is probably one of the chief causes of past failures in treating severe diabetes. In the severe cases it is found necessary to restrict all classes of food, and to test the tolerance of each patient for each particular class. Carbohydrate is given if possible, but is kept safely below the limit of tolerance. Protein must be kept fairly low, sometimes very low. With a dangerously low protein tolerance the working rule has been to exclude all carbohydrate, then feed as much protein as is possible without glycosuria. Experience thus far seems to indicate that every patient can tolerate his necessary minimum, and that glycosuria appears only when this indispensable minimum is exceeded; but a longer series of analyses will be necessary before asserting this as a fact. Fat has heretofore been considered as both safe and necessary in the diabetic diet. I realize the risk of disputing this doctrine, but must state the observation that patients may show a fat tolerance as truly as a carbohydrate or a protein tolerance. I have never seen glycosuria from fat alone; but there are patients whose urine is constantly neg-

ative on a given diet, who will show both glycosuria and ketonuria if butter or olive oil is added to that diet. The very severe diabetic may be both thin and weak, because he cannot metabolize enough food to be strong or well-nourished. But as long as his weakened function is not overtaxed, he seems able to retain such weight and strength as he has, at least for a considerable period. Any attempt to build him up with any kind or quantity of food beyond what he is able to metabolize perfectly, apparently hastens a fatal result.

The number of diabetics admitted to the Rockefeller Hospital has been twenty-seven. The majority were admitted only during the past month, therefore are still in the Hospital. The longest treatment and observation of any one patient has been nine months. The number of applications has considerably exceeded the accommodations, therefore selection has been possible. No very severe case has yet been rejected, and the policy has been to choose the worst cases of diabetes that could be found. Lately a few earlier or milder cases have been admitted, in order to learn what can be done with such patients. The youngest patient is aged ten. The oldest is a woman of sixty-nine, with incipient gangrene. Every patient treated has been made free from both glycosuria and acidosis. The number of deaths has been three. Of these two were untreated cases; viz., one man who entered the hospital in coma and died within three hours, receiving no treatment except an intravenous bicarbonate injection; and one woman who entered with acute heart failure and hemoptysis, and died on the fifth day, apparently from her cardiac lesion. The one treated patient who died was a twelve year old boy, who had had diabetes for seven years, the long duration being perhaps partly explained by the excellent care he had received. The emaciation was extreme; there had been albuminuria with casts for several months; he was almost totally blind with diabetic retinitis; he had been in partial coma on several occasions, and coma had been feared for several days before he entered the hospital. This boy became free from glycosuria and acidosis, and showed very satisfactory improvement for two and one-half months. He was taking a diet of sufficient quantity, and had acquired a tolerance of twenty grams of carbohydrate. He seemed to cooperate very cheerfully in the treatment as long as the fear of death was upon him, but as soon as he imagined himself out of danger, he showed surprising ingenuity in stealing food. Several such adventures caused him to lose ground seriously, and he died in a rather sudden and unexplained fashion, with urine still sugar-free, four months after entering the hospital. The essential cause of death was his extreme weakness. Accordingly, up to the present, the record is that no patient has died who has followed treatment. Deaths are to be expected, however, if we continue to accept the most extreme cases; and there

is no desire to pretend that this treatment can save all patients.

The graphic charts shown here represent the records of four patients. These charts and analyses are made by or under the supervision of Miss Mary B. Wishart, as chemist.

The first chart is that of a man aged 34, with moderately severe diabetes of one year's standing. He originally weighed 175 or 180 pounds, without obesity, and he had lost fifty pounds. There was considerable glycosuria on ordinary strict diet; in two days' test on admission the output was 32 to 61 grams. There was a positive ferric chloride reaction, but no clinical symptoms of acidosis; and as we were busy with more severe cases, no quantitative determinations were done except for sugar. Four days of fasting were required before the urine was sugar-free. That is one indication that the diabetes was not very mild. Ketonuria ceased as usual. The diet was gradually increased, and the improvement was satisfactory. Then an experiment was started with quantitative determinations, and the chart shows how both glycosuria and ketonuria returned when fat was added to the diet. As this was a fairly mild case, an enormous quantity of fat was necessary to produce this result—more fat than the average patient could eat. Everything then cleared up promptly under treatment. He gained weight and was dismissed to resume his ordinary work, on adequate diet, but with orders to keep himself at least fifteen pounds below his previous weight.

The second case is a little more severe. The patient was an Italian tenement-house girl, seventeen years old, with diabetes of eighteen months' standing. One year ago she spent seven weeks in Mt. Sinai Hospital. The diabetes was not stopped, and she was dismissed, taking sodium bicarbonate and a limited quantity of bread. Before the diabetes she was slightly obese, weighing 120 pounds. Her weight when we received her was 92 pounds. On ordinary strict diet her urine showed 78 grams sugar, 11.7 grams acetone bodies as B. oxybutyric acid, and 3.1 grams ammonia, on 20 grams of sodium bicarbonate daily. She cleared up in the usual way and progressed satisfactorily. Her symptoms were reproduced by adding chiefly fat to the diet, and were cleared up again by the usual treatment. She was dismissed to go to work, on adequate diet, with urine normal, feeling perfectly well. She was not allowed to gain weight, and was ordered not to gain weight after leaving.

The third patient is a man aged twenty-nine, with diabetes of eighteen months' standing and unusual severity. He was thin and slight at his original weight of 145 to 150 pounds, and he entered the hospital weighing 110 pounds. He had been in the best of hands, but was never sugar-free from the outset. He was sent to us from the Presbyterian Hospital, where he had been for ten days in a dangerous condition. They had found the D:N ratio of the totally depancreatized dog, viz, about 2.8 to 1. We confirmed this in a four days' test on carbohydrate-free diet. During this time he was shooting downward with remarkable rapidity. While eating to his utmost capacity, he lost about a kilogram of weight per day, with a negative nitrogen balance of from 12 to 16 grams per day. Sugar excretion was

58 to 65 grams, acetone bodies 20 to 39 grams, ammonia 2.88 to 4.25 grams. Treatment had to be begun because he was going into coma. The chart shows the subsequent progress, during his four months in the hospital. So far, this record is the most unsatisfactory one we have, and I show it for that reason. There is no ketonuria, but the occasional slight glycosuria is bad, and is only partly explained by intentional dietary tests. There is no immediate danger, and the patient feels much better and more comfortable in every way than before treatment. He can be up and dressed all day, and can take a little exercise or go to the theatre. But he is thin and weak, unfit for work, and still in need of hospital care. His future is doubtful.

The fourth patient is the most severe we have had. He was a strong, healthy Irish boy, aged seventeen years, apparently absolutely normal until the sudden onset of diabetes ten months ago. He had chiefly dispensary treatment, and was twenty-five days in Bellevue Hospital last June, but the diabetes was never stopped. His normal weight was 133 pounds. He came to us weighing 91 pounds. He had just had a severe gastro-intestinal upset with weakness such that he was expected to die, and came to the hospital as soon as he was able to leave bed. His blood-pressure was 85 systolic, 75 diastolic. He was sent to Bellevue Hospital for calorimeter tests by Dr. DuBois in connection with the treatment, and has remained there up to the present time. I am indebted to Dr. DuBois for all the records and analyses except those of the acetone bodies. The preliminary tests were cut short because coma seemed imminent. The most interesting data are that on Nov. 11 he received no food except 50 c.c. cream early in the morning, and subtracting the carbohydrate of the cream, the D/N quotient on this day was 3.69.⁹ The blood-sugar on this day was 0.3%. The respiratory quotient was 0.697, indicating the combustion of little or no carbohydrate. The chart shows the subsequent history to date. It is noteworthy that the blood-sugar has declined, but has never yet reached normal. This is the only case, among several tested, in which the blood-sugar has not fallen promptly to normal. The diet now consists of meat, eggs, butter, olive oil, whiskey, and thrice-cooked vegetables, representing a maximum of 9.77 grams nitrogen and 1991 calories daily. A trace of glycosuria appeared on this maximum diet, which has therefore been slightly reduced. The patient is subjectively improved. The respiratory quotient indicates that the protein sugar is now burned. The marked gain in weight is essentially water-storage, which perhaps represents partly a normal recovery of water by the previously dried tissues, and perhaps partly an invisible edema.

These cases afford a general idea of the methods and results of this treatment. There seems evidence that it clears up certain cases which heretofore have not been cleared up, and that the cases which could be cleared up heretofore are cleared up more quickly by this method. Of course it is not a "cure" of diabetes; and essentially the new feature in it is that, upon the information gained from animal experiments, it attempts to do the same things that the rational treatment has attempted previously, but to do them more quickly and accurately and thorough-

ly. The immediate results are what we can state. The permanent results are yet to be demonstrated, and they are the most important. As friends here in Boston have told me, what they wish will be to know, one year, two years, and at longer periods hereafter, how many of these patients are dead, how many are free from glycosuria and other symptoms, how many are fit for work or play, and so forth. These are in fact just and decisive questions. The answer to them will be governed by two factors, one of which may be called the scientific factor, and the other the human factor. It is worth while to discuss these two factors, to give some idea of the hopes and possibilities.

The scientific factor has to do with the theoretical value of this treatment under ideal conditions. What are its powers and its limitations, provided it is perfectly carried out? It seems possible that it may offer the hope of abolishing, in diabetes, all those things which have traditionally been considered as practically synonymous with diabetes. It gives the vision of a diabetes in which there is no glycosuria, no acidosis, no use for alkalies or other drugs, no complications, no gangrene, no downward progress, no coma, no death. That is the ideal which I venture to put into words, without knowing whether the future will justify it or not. The vital question must be decided: Is there or is there not an inherent downward tendency in diabetes? The answers of the past are not conclusive, because there has been too much overfeeding with carbohydrate-free diet. If the pancreatic function is spared by keeping the total diet low enough and the body weight low enough, will there be any spontaneous downward tendency? All that can now be said is that in the longest observation, namely nine months in a severe case, the condition is still good. But the most severe cases cannot give the answer. To keep these patients alive at all probably involves a strain upon the pancreatic function, comparable to the strain of excessive carbohydrate-free diet in the milder cases. This girl who has been in the hospital for nine months has improved subjectively and seldom needs fast-days, and is expected to go home before long; but when it was attempted recently to add half a small grapefruit to her carbohydrate-free diet, the result was an immediate glycosuria which required a fast-day to stop it. In these other cases, the addition of a few grams of protein or fat makes trouble. That is how close the margin is, and it is too dangerously close. It may be considered probable that these very severe cases will go slowly downhill, and that treatment can merely prolong their lives and keep them more comfortable, without saving them. From the experience with milder cases, we might think that when these very severe patients are kept free from glycosuria for several months continuously, their tolerance ought to improve. So far, this hope has been disappointed. Gain in tolerance marks the milder cases. In the cases of utmost

severity, it is as if the trouble were organic, or as if the breakdown, if functional, were beyond repair. An interesting theoretical question is raised as to the reason why apparently all patients, even those with total diabetes, can be free from glycosuria and acidosis if brought to a starvation level, but cannot tolerate any attempt to raise them much above this level. From a practical standpoint, even under ideal conditions, I cannot see much hope for the third and fourth patients described here. The second would make an interesting study if she could be kept under ideal conditions. The first patient is much more hopeful. The important practical point is that patients should never be allowed to reach any such condition. All four of these patients came under medical care near the outset of their trouble, but the physicians did not stop the glycosuria or the ketonuria in a single one of them. A boy of sixteen years has recently been admitted to the Hospital with heavy glycosuria of only a month's duration. His urine was made normal in two days, and he will be dismissed with a favorable prognosis conditional on good behavior. The cases of utmost severity are really useful chiefly as tests to demonstrate the benefits of methods which should be applied to all cases before they become severe. If there is ever to be the ideal epoch of treatment which I mentioned above, it can come only through the application of efficient, intelligent methods by the great mass of general practitioners, who are the ones that see the great mass of diabetics in the early stages. When such methods are used from the outset, we shall have opportunity to learn whether downward progress in diabetes is inevitable.

There is now to be considered the human factor. This involves recognition of the important fact that conditions are seldom ideal, human nature is imperfect, and the treatment is long and onerous for both physician and patient. Nevertheless, one of the principal hopes that I have for this treatment is that it will prove useful in assisting the human factor. This proposition may be discussed in relation to the physician and to the patient. However specialists may feel, there is no doubt that a majority of average practitioners feel bewildered and helpless concerning diabetes. The widespread use of drugs, proprietary nostrums, and various irrational treatments probably indicates not so much confidence in these things as ignorance of other means to use. Granting that the principle is correct, there should be considerable value in impressing physicians at large with the idea that diabetes is merely the weakness of a bodily function, not a progressive fatal disease. Many physicians fear to withdraw carbohydrate, if the withdrawal causes any marked ketonuria. Accordingly, they give carbohydrate and thus send the patient downhill with continuous glycosuria.¹¹ The treatment above described will stop glycosuria very promptly, and instead of producing ketonuria will abolish it if it already exists. It will

be beneficial if the general medical profession comes to realize that the interests of the patient require the stopping of both glycosuria and ketonuria, and that it is possible to stop these things within a very few days.

Taking up the patient's side of the matter, it can be said that no one has yet refused to take the treatment. The treatment is rigorous, especially in severe cases, but every patient has reported increased comfort, and has preferred to endure the low diet rather than to return to what he suffered before beginning treatment. Gastro-intestinal troubles are absent. The patients have shown none of the carbohydrate hunger which is supposed to belong to diabetes. When asked what they would like to have added to the diet, they have said bacon more often than bread. In view of the opportunity to choose patients, the question arises as to what sort should be selected. The choice might be limited to intelligent, well-to-do, careful persons, and thus an attempt made to show what can be done under ideal conditions. This might be called an unfair test, since most physicians and hospitals cannot thus select their patients. Therefore up to the present, patients have been selected solely on the basis of severity, without regard to character, intelligence, or surroundings. Also, it could be arranged to keep all these patients by themselves. But since some hospitals cannot do this, most of our patients are now kept in wards along with cardiac and other cases, where they might steal food if they tried hard enough, and where they can see trays of bread and desserts going to other patients. These are conditions which they must face when they leave the hospital, and they might as well be accustomed to them. There has been practically no trouble on this account. By taking patients who are poor, ignorant, careless, and lacking in self-control, it is made certain that our statistics will suffer. Some of these patients will promptly relapse, and others will drop out of sight and never be heard from again. These conditions must all be faced, in order to learn what can be done with the ordinary run of patients. The ultimate results will fall easily into two groups. When the patients follow instructions carefully, we shall learn what happens under good conditions. If they go downhill under these conditions, the scientific factor will be at fault; this will be the test of it. But when the patients fail to obey instructions and proceed to eat bread and potatoes, this will have nothing to do with the theory of the subject, and will represent merely a failure of the human factor.

It will be of interest to know whether our method can help this factor. Most patients of all classes desire to live, and desire to be free from the symptoms that trouble them. Our severe cases have nearly all been told elsewhere that they must die, and even the milder ones generally have a wholesome fear of the word diabetes. It seems to make a very good beginning when they are told that their glycosuria will cease

within a few days; that they have not a mysterious fatal disease, but merely the weakness of a bodily function, like a weak stomach, and that it is entirely their own responsibility to live or die. Even for the patients who could be cleared up within a few weeks or months by the older methods, it seems an advantage to clear up the urine within a few days, and devote the remaining time to getting the patient accustomed to his diet and teaching him to take care of himself. On leaving the hospital, the patient is given orders as follows: to save and test his urine every day by Benedict's method, which even the ignorant can learn; if sugar appears, to check it instantly by a fast-day and then reduce his diet somewhat; to take a fast-day in bed at stated intervals, generally once in two to four weeks, even if sugar does not appear; to live on a diet of certain articles of food in certain approximate quantities; and instead of weighing the diet, to weigh himself at least once a week, and never let his weight rise above a stated figure. This figure is always below his original maximum weight, and is made lower in proportion to the severity of the diabetes.

As mentioned before, only the immediate results are stated as facts, and time must decide concerning the permanent value of the method.

SOME PERILS CONFRONTING STATE CARE OF THE INSANE.*

By CHARLES P. BANCROFT, M.D., CONCORD, N. H.,
Superintendent, State Hospital, Concord, N. H.

THE purpose of this paper is to call attention to old evils appearing in more virulent form at the present time. The centralized management of all state institutions, quite popular throughout the country, makes a brief review of the history of the public care of the insane both pertinent and instructive. The history may be roughly divided into three periods: first that of

* Read before the Boston Society of Psychiatry and Neurology, November 19, 1914.

neglect, second of mixed care, and third of state care.

The period of neglect began in early Colonial times and extended through the first days of the republic to the beginning of the nineteenth century. The failure to properly provide for the insane during these early years may be attributed to infrequency of the disease, and profound misconception of its real nature rather than any lack of the true spirit of charity. In the very earliest Colonial days one may possibly trace a certain portion of this indifference to the austere religious conception of life characteristic of the Puritan. These serious religionists may have regarded the misfortunes of the insane as a judgment of God upon some moral perversity or short-coming. It is conceivable that their mental attitude may have curbed any feelings of sympathy which might naturally be awakened by the sufferings of the mentally afflicted.

Probably infrequency of the disease during the Colonial period was the most prominent underlying factor in this early neglect of the insane. During this period there were few insane, not merely because there was a sparse population, but because the early colonists were strong virile men and women. There were few weaklings. These first settlers were both mentally and physically the best equipped of their race. They were the ambitious adventurous pioneers, anxious to secure for themselves larger liberty in a new land. The very qualities of mind and body that led them to renounce the easier life in their native land and endure the privations and hardships of a new and unsettled wilderness were inconsistent with brain weakness. Insanity was rare because these earlier inhabitants for the most part possessed sound minds in sound bodies. Apparently mental defect was so infrequent that communities regarded as freaks such sporadic cases as did occur, rather than mentally diseased persons whose maladies might reappear in others and require special care. This disregard of insanity was a logical result of the prevailing misconception of its real nature. Consequently defective and insane persons of the early Colonial period were, if poor, allowed to roam at large with little or no care. Among families of means such cases were segregated and cared for at home as well as circumstances would admit.

Eventually the increasing number of mentally diseased persons made some sort of recognition imperative both for their own safety and that of the community. It was evident that public care in some form must be adopted. The problem, being a local one, its solution was sought within the conventional boundaries of the township. The town officials were called upon to care for their own insane as best they could, in the poorhouse or other extemporized way.

In some states, especially the less populous, the town system of care was felt to be inadequate. The numerically small town and the

town with limited finances found the expense burdensome; they could not provide suitable and in some instances even decent care. As facilities for intercommunication multiplied, the mutual interests and common relationship between towns in the same county became more manifest, with the resulting conviction that the county could furnish better care for all the insane within its boundaries than the towns acting independently. In these states county farms with large acreage and many buildings were established, and the old town poorhouses were closed. The result was greatly improved care of the insane. The larger unit not only provided better care, but under this system there was a diminished feeling of disgrace in the mind of the recipient of this form of public charity. The closer the donor to the beneficiary, the more intimate the personal relationship between the two, the more keenly does the recipient feel his misfortune.

As has been said, the period of mixed care, roughly speaking, began in the early days of the nineteenth century. With few exceptions, at that time the majority of the insane were maintained at the expense of the towns. Town care was generally accepted as the only method of public provision for the dependent insane. Early in the nineteenth century an awakening to the needs of the insane appeared. Partial state care was advocated, a method which received staunch support in Miss Dorothea Dix. The movement spread throughout the country, and state institutions appeared throughout the land. While these were nominally state institutions, no attempt was made to provide within their walls for all the insane in any state, nor was entire state support of all the patients admitted contemplated at that time. During this period of mixed care the dependent insane were supported and cared for by the town, the county, and the state in the three different classes of institutions enumerated.

During all these years experience was demonstrating that in the field of public charities and corrections the state is better fitted for the administration of the complex problems involved in the care of the insane. It is now generally conceded that of the three administrative units—town or city, county, and state—the latter is the one best equipped for the successful care of the insane, involving as it does intricate questions of treatment, prevention, after-care and scientific research. The slow evolution of state care from the remote days of neglect is evidence of the soundness of the consummation attained. The principle of state care achieved only after years of experience and mature conviction is unquestionably logical and correct.

When the asylums, as they were formerly called, were first established, their management was modeled after that of the general hospital, viz., boards of unsalaried trustees, whose only compensation was their travelling expenses.

The governors of the several states selected for these positions, business, professional, and scientific men, whose interest in the work would be assured irrespective of any remuneration. This plan has always proved most satisfactory in the government of either public or private charitable institutions. Partisan political affiliation played no part in the selection of these trustees. The result was a disinterested service freely given by men of the highest ability. The very fact that there was "nothing in it," in the sordid political sense, kept away "grafters" and secured permanency of service. At first only men were appointed on these boards, but later and long before the present feminist movement began the need of women's assistance was realized and two or more women were almost invariably represented in the personnel of the boards. The advantages accruing to the state from this form of institutional polity are economy to the state, continuity of service, elimination of politics from the conduct of state charities, and a certain definite zeal and interest in the work that comes from the intimate personal association existing between the superintendent, his medical staff, and the managers of the institution. The more impersonal and the farther removed from the daily life of the hospital is the board of managers, the less the interest and the more mechanical becomes the service. The more intimate the personal relationship between a local board of interested trustees and the superintendent and his patients, the more positive will be the impression upon the hospital. In fact, the successful hospital is the reflection of the character and devotion of its board of managers and their superintendent. Hospitals, like persons, have an individuality, which, after all, is merely the expression of the devotion, enthusiasm, and experience of those in charge.

The government of the state's charitable institutions by unsalaried boards of trustees has the distinct advantage of stimulating a general public interest in such charities. Undoubtedly this idea primarily suggested the management of the general hospitals by unpaid trustees. Society does and should take an interest in the benevolences of the state. Such interest should be fostered and utilized in every possible way. If professional and business men, or those with leisure and large experience in charitable work, are willing to devote their time and energy without remuneration to the administration of our public charities, by all means should such service be accepted and encouraged by the state as a civic obligation of its citizens. Not only is economy secured to the state by such gratuitous service, but a zeal and spirit of devotion is attained that is invaluable. One of the chief objections to the old town and county care of the insane under partisan political appointees was the indifferent service rendered by such management. Scientific study, proper classification of patients, and intelligent care were too often

sacrificed to a spirit of petty political economies, which lost sight of the real purpose of the charity.

Within recent years an entirely different system of institutional polity has arisen. Under this method all the state's charitable and penal institutions are placed under the management of central boards of control, with offices at the state house. The local boards of trustees, who met at the institution over which they were appointed, are abolished. The board of control usually consists of three members, who have salaries and are appointed with some reference to their party political affiliations. Women are not represented on these boards and consequently are not represented in the management of any of the state institutions. The new system, beginning in the West, has recently moved rapidly eastward, and for obvious reasons has become quite popular with the politicians. A fancied economic saving to the state has, however, prejudiced many well-meaning persons in its favor. Misled by specious reasoning, based on a somewhat illusory theory that administration of the state's charities by a board of control is founded on sound business principles and that a great saving to the state is to be thereby effected, these very fair-minded persons hastily subscribe to the new doctrine without sufficient reflection as to whether the new polity is really economical and most desirable in the long run for the administration of the state's charities. It may be well to consider carefully the merits and demerits of a system which threatens to abolish an institutional polity that has had the sanction of time and experience and which still is the only recognized form of institutional management in all private charities. With the general acceptance of this principle of state care of all dependents, attention has been directed as never before to the magnitude of the expense involved. This expense was not as noticeable when divided among counties and towns, but when presented in the aggregate in a single lump sum looms up as one of the largest financial burdens that the state has to carry. Central supervision over this expenditure is both logical and necessary. The principle of centralization in business management is sound and there is no reason why a state in the direction of its charities should not be guided to a certain extent by the same economic considerations that prevail in the business world. At the same time there is a difference in the final purposes of a large business organization like the Standard Oil or the U. S. Steel Corporation, whose sole ambition is financial return to stockholders, and the charities of a state, whose chief mission is the alleviation of human suffering. In the attempt to centralize the management of all state charitable institutions there is a real danger that the original mission of these charities may be sacrificed to an arbitrary and mechanical business theory. Economic administration of

the state's charities is only one side of the equation. As at present constituted, boards of control attempt a double service for the state,—fiscal supervision and administrative control of the institutions. These two functions, although closely related, need not necessarily be imposed upon the same board. While the steadily increasing cost of maintenance renders fiscal supervision by the state necessary, it does not follow that administration of the institutions can be more economically or more satisfactorily conducted by central boards of control than by carefully selected unpaid boards of trustees.

In the management of the state's charitable institutions we find then that fiscal supervision and administrative control are the two desiderata. The problem is to so correlate these two phases of institutional polity that the best interests of the wards of the state may be conserved with the least possible expense to the state. In the new system of centralization the fulfilment of this double obligation is placed upon the board of control. The wisdom of this course is questionable. While centralization may be desirable in the control of expenditures and possibly in the purchase of supplies, its application to the administrative detail of the institutions may be unfortunate.

With certain slight differences in the various Western states, boards of control as originally devised were composed of three members, with salaries of \$3500 each, or thereabout. These boards appointed the superintendents and purchasing agents for the institutions, and assumed the administrative and advisory functions that formerly belonged to the trustees. These boards had exclusive control over the finances and management of the penal and charitable institutions of the states. In many states local boards of visitors were appointed without pay except for traveling expenses, a sort of concession for the removal of the trustees. Women were represented on the board of visitors. It is significant, however, that these visitors are not responsible for the management of the institution, practically have no authority and naturally lack initiative. These visitors are practically figure heads, replacing the former trustees. The distinguishing characteristics of the new system are the central government of the institutions in both their physical and financial aspects, the divorce of the business and medical management of the hospital, and the obliteration of the individuality of the several institutions.

With presumably economical intention many modifications of this original scheme have appeared without, however, increasing the efficiency. In New Hampshire a board of control has been appointed with the purchasing agent as a member. This purchasing agent receives a substantial salary and devotes his entire time to the work, while the other members receive a *per diem* remuneration and devote such time as in their judgment seems advisable. Modi-

fications of the original plan in the interest of economy are questionable. It would seem advisable that if management by a board of control is adopted the members of the board should devote their entire time to the work, even though the expense is larger.

In still another state the following rather complicated plan has been proposed which would certainly have the merit of providing many salaried officials with positions involving large expense. This plan provides a central board consisting of five members with salaries of \$1000 each, whose functions are general and advisory. The central board appoints a director. This director must command a large salary, for he is endowed with vast powers, including the appointment of four assistant executive secretaries with large salaries, a business agent, the superintendents of the several institutions, as well as supervision and control over everything pertaining to the administrative and financial affairs of the hospitals, including all new construction. Under the director the four executive secretaries come into immediate contact with the details of the institutions, in a way replacing the former unpaid trustees. The business agent executes the orders of the director and appoints a purchasing agent, with offices, clerical force, and facilities for purchasing and storing supplies. Last, is an unpaid board of visitors, who have no authority except that of listening to complaints, which they cannot correct personally, but may report to the central board. This somewhat involved plan provides control galore. First a central board, second a director, third four executive secretaries, fourth a business agent, and fifth a purchasing agent with expensive offices, clerical force and storehouses. This plan, much more complicated than any previous method, is the latest academic creation of the professional efficiency expert. It is difficult to see how either efficiency or economy can be secured through such a complex and expensive organization. Whatever modifications of the original plan of centralized control may have been adopted, the ultimate purpose has been the withdrawal of local management from the institutions and the substitution of a central board with plenary, fiscal, and administrative power. Assuming that these two functions can be separated, what are the objections to administrative management of state institutions by a central board? First, too many and varied duties are imposed upon a single board. It is questionable whether three or even five officials at a central office can be of as great service to the charitable and penal institutions as local boards of trustees in close touch with individual institutions. The amount of time which a central board can give to the administrative details of many institutions of diverse character, situated in widely separated localities, must of necessity be quite limited. The problems vary greatly in the different institutions. Those of the feeble-minded

schools are not identical with those of the insane hospitals. Even the institutions for the insane differ among themselves. The hospitals for the acute, the chronic, and the criminal insane present peculiar and special problems, whose solution demands more time than a single central board has at its command. Neither can these special questions be satisfactorily settled by a board of visitors upon whom rests no final responsibility. What incentive or satisfaction can a board of visitors experience who feel they have no responsibility and who do not know that their suggestions or advice will be heeded by the real managers?

Second, lack of sympathy between the central board and the various hospitals. Successful administration of hospitals and charitable institutions depends directly on the active sympathy and personal interest of their boards of managers. Such interest can only be secured by intimate personal contact, frequent visitation, and close familiarity with the inner working of the hospital, and acquaintance with the actual needs of the patients. Weekly conferences at some central office between the superintendents and the board of control are not as helpful and stimulating to the superintendent as were the frequent visitations of the trustees and their meetings at the hospital, with free opportunity for consultation and helpful suggestion. A central board of control, with many duties and numerous widely separated institutions for visitation and supervision, must give brief and perfunctory service to each. The very fact that it is physically impossible for the board to give the necessary time to the several hospitals renders the service mechanical, and deprives the superintendent of the advice and consultation he so much needs. It is doubtful whether a board of control, visiting many institutions, can ever be in as close sympathy with the work of any particular institution as a local board of trustees who are devoting their time to the service of that institution alone.

Third, the elimination of women from any participation in the management of the hospitals. The principle is now firmly established that women should be represented on the boards of managers of any institution caring for women and children. Whether it is because members of boards of control are really political appointees, or because women are not supposed to be equal to the larger duties attaching to this service, it is significant that whenever trustees of state hospitals have been replaced by a central board of control, women have not been represented in the new management. In some states women have been relegated to the inconsequential boards of visitors, which really means that they have been removed from all actual participation in the activities of the hospitals.

Fourth, the possibility of politics entering the management of state charities. Under this system, the danger is always imminent that par-

tisan political preference may determine the personnel of the official board directing the state's charities. Government of state institutions by boards of trustees possessed this one great merit, that the men and women composing these boards were selected solely because of their fitness, without any reference to their political affiliations. General fitness and adaptability for the work and not political patronage should determine the selection of men for these positions. It is willingly conceded that most excellent men have been and still are being appointed on these boards of control, but the possibility that political considerations may at any time influence their selection is a menace. State charities should be as free from political interference as private charities. Fifth, the principle that the medical administration must be separate and distinct from the business administration, is not sound in theory nor beneficent in practice. In institutions ministering to human illness or defect the medical and the business relations are so intimate that complete separation is not possible without defeat or impairment of the very work for which these institutions stand. Any plan that seeks the divorce of the medical from the business administration is in danger of commercializing charity. The state hospitals for the past twenty-five years have been steadily assimilating the true hospital spirit. Treatment has been assuming greater prominence. The old almshouse treatment of insanity, based on economy carried to parsimony, has well nigh disappeared. The state hospitals have entirely reformed these obsolete methods. Trained nursing, carefully prepared dietaries, study of individual cases with proper treatment, both medicinal, psycho-therapeutic, and hydropathic, industrial employment, pathological research, prophylaxis, field work, and after-care all enter into the work of the hospitals, and are all essential medical questions. Any attempt to isolate and withdraw these activities from the business administration of the hospital is impossible. The general hospitals have long since demonstrated that the medical and the business administration cannot be separated without detriment to the usefulness of the hospital. From this let it not be argued that extravagance will follow, nor that it is desirable or necessary. The real problem is, how the business and the medical administrations may be correlated, and some workable plan devised by which the mission of the hospitals may be efficiently and economically realized.

It is not absolutely certain that central purchasing by a single purchasing agent is as economical as local purchasing by the institutions under competitive bids with central fiscal supervision and audit. The purchasing of supplies for a hospital is not identical with the purchase of supplies for a large railway or mercantile corporation. The character of many of the goods used in hospitals, the danger of dete-

rioration, and the expense of central storage and distribution render the economy of this method doubtful. Such plan can only be economical in large states with many institutions of a single class, and even then is of doubtful value.

In his exhaustive analysis of the "Methods of Fiscal Control of State Institutions" made for the State Charities Aid Association of New York State, Henry C. Wright finds that of the three methods of supervision studied, namely, those of New York, Iowa, and Indiana, the greater saving was in Indiana, in which state the institutions are managed by local boards of trustees under the supervision of a state board of charities. "The larger costs noted in connection with New York and Iowa are, in large measure, the cost of supervision of details of the administration of the institutions, which, in Indiana, remains in the hands of the superintendents of the institutions. These details are handled as satisfactorily by the superintendents in Indiana as by the central supervising officers in New York and Iowa." Undoubtedly in this statement lies the exact truth,—any theoretical saving by central administration is more than offset by the increased expense of maintaining the system.

There is no reason why, under a well-devised plan of coöperative and competitive buying, the institutions cannot purchase goods of the same quality as economically as a central purchasing agent. It is easily possible for a man, intent on buying only the cheapest goods, and unfamiliar with institutional requirements, to purchase inferior articles, the attempted use of which will cripple the efficiency of the institution. In a hospital the judgment of an experienced medical superintendent may be wiser than that of a lay buyer, unfamiliar with the real needs of the institution. On this point Mr. Wright says: "It seems difficult for the fiscal supervisor to bear in mind that the primary function of the institutions under his charge is, where possible, to heal and reform. There is a mass of evidence which will make it appear that his first concern is for small economies rather than for efficiency in operation."

In those states where boards of control have been or are about to be established, many of the evils of such a system can be forestalled by having at least one woman on the board, by holding stated meetings of the board at the various institutions at least once a month, by making the purchasing agent, where such an official exists, an agent and not a member of the board, and by legislation requiring the board to give their entire time to the work, with such remuneration as will secure an able and efficient personnel. Merit and experience, and not partisan political influence should determine the selection of the membership. The presence of a woman on a board of managers having the custody of women inmates in various institutions is most desirable.

In countless administrative matters her experience and point of view may prove most helpful. Her active presence in meetings would contribute greatly toward removing the charge and danger of political bias. By holding regular monthly meetings at the institutions, the board comes into more intimate and personal relations with the institutions and their work than when board meetings are held at a central place, as the State House. The management of the institutions in consultation with the board of control, and not the purchasing agent, should standardize and determine the selection of goods, not an independent buyer whose sole aim may be price, not quality, and who personally may be quite unfamiliar with the actual needs of the institution.

In Maryland a most admirable system of co-operative buying has been adopted in the state institutions. According to this plan the hospitals have a central bureau, to which all requisitions are sent at stated times. All institutional supplies are standardized and samples are on exhibition at this office. From this office advertisements for proposals are sent out and contracts signed with the lowest bidders. Little expense is entailed under this method, and the institutions secure the class of goods they require at the lowest possible cost.

The peril that at the present time menaces state care of the insane is excess of control. The institutions and the officers who manage them may become so hampered by petty supervision as to lose efficiency in operation and management. Just as the overtrained athlete loses his spirit and his nerve at the crucial moment, so will the hospitals under excess of control forfeit the true hospital spirit and the initiative that formerly prevailed. There is danger that they will become mere receptacles for housing and feeding large numbers of inmates without showing any very great financial saving for the state, thereby losing sight of the scientific and therapeutic aims for which these institutions stand.

After all why is this expensive machinery of control necessary, unless to provide many more high-salaried officials? Mr. Wright in his report with great justice states that what the institutions and the superintendents most need is advice of experts, uniformity of accounting and reporting, and standardization, as far as is possible, of all hospital supplies. The securing of these considerations does not require complicated and expensive supervisory boards. What is really needed is central fiscal supervision, with as large a degree of local independence as is necessary to secure efficiency and economy.

Mr. Wright's recommendations contain much that will appeal to the trained institutional worker. A central supervising board, serving without pay, and having "function of inspection, recommendation, and advice, combined with a partial power of control." This board to have as salaried secretary a man of "marked

ability," and familiar with institution requirements, and also empowered to employ experts, as they may be needed to give advice on all matters pertaining to the life and well-being of the institutions. Boards of managers with women representatives appointed for each institution by the governor. Advisory relations to exist between the supervising board and the managers. Stated conferences between the superintendents and the managers. Joint purchasing of supplies with such expert advice and laboratory tests as the supervising board may deem necessary. Under some such general scheme the state will maintain control over all expenditures, its interest in and direction of its charities will be attained with the smallest possible outlay. Individual civic responsibility to the state will be secured through volunteer workers. Public charities and correction will not be imperilled by partisan political interests. Efficiency, economy, continuity, and permanence of service will characterize the management of our state institutions.

THE PRE-OPERATIVE DIAGNOSIS OF TUBERCULAR MESENTERIC AND RETROPERITONEAL GLANDS.

By EDW. H. RISLEY, M.D., F.A.C.S., BOSTON.

Assistant Surgeon to Out-Patients, Massachusetts General Hospital.

WITH the advent of greater perfection in the technic of the Roentgen ray examination and diagnosis of abdominal conditions there is still felt the need of greater refinement of diagnosis of the acute conditions, especially of the right lower quadrant.

The clinical investigation undertaken in this paper was stimulated by the recent occurrence in the author's practice of several cases strongly simulating appendicitis and distinctly of the operative type, but which on opening the abdomen, were found to be what I think we can properly term the acute fulminating type of retroperitoneal or mesenteric adenitis of tubercular origin.

The attempt is made in this paper through the analysis of a series of autopsy and clinical records to throw some additional light on the pre-operative diagnosis of this condition,—primary retroperitoneal and mesenteric tubercular adenitis.

The type of this disease, which is secondary to general or intestinal tuberculosis, is not considered in this paper, but only that type which has recently come to be recognized as a definite and separate clinical entity, but which so often simulates and is mistaken for the acute conditions occurring in the right lower quadrant of the abdomen.

This type of case occurs quite frequently in

both private and hospital practice, especially in children and young adults.

Clinical surgical experience shows that there are certain cases which present a definite picture of an acute right lower quadrant condition, most often simulating appendicitis, which on operation show a normal or slightly congested appendix and no other pathology than masses of retroperitoneal glands in various stages of enlargement and in which no other tubercular foci can be found anywhere in the body on most careful examination.

These isolated glands or groups of glands may occur anywhere in the mesentery, but are most commonly found in the ileo-cecal region.

Corner, who seems to have had considerable experience with this class of case, and to whose papers many references are made in the literature, thinks that there is a physiologic reason for this location in the comparative stasis of the products of digestion in a mildly alkaline medium at this site; a condition which favors the passage of tubercle bacilli through the intact mucous membrane of the bowel.

Corner also believes that tuberculous mesenteric glands are to be found in practically every child in which an abdominal operation is necessary. This great frequency and the fact that glandular (non-tubercular) enlargement is so common in other regions of the body in children coincident with any pathologic condition, makes the raising of the question of the tubercular nature of these glands in children a pointed one.

There are many reported instances in which the removal of an apparently normal or only slightly congested appendix was followed by the subsidence of all symptoms and even by the disappearance of glandular enlargements. And whether we grant that this mesenteric adenitis, in very young children, is of tubercular origin or whether it be a simple adenitis so common in all inflammatory or other conditions in young children, the facts still remain that this type of disease often does produce a chain of acute right lower abdominal symptoms of such a type as generally to demand surgical intervention. It seems arguable to the writer that as these glands are so commonly found in many conditions in young children, for which the abdomen is opened, and as these children ultimately go on to complete recovery from their surgical condition and do not suffer in the future from further enlargement of these glands, therefore we may believe that a mesenteric adenitis is a common condition in children, from which they recover spontaneously, also from which it is the exception rather than the rule to have symptoms; that these are probably more likely to be of inflammatory than tubercular origin and from which they may be expected to recover without further morbidity.

When we discuss this condition in adults, however, it seems reasonable to suppose that glands which have persisted since childhood or have developed recently are much more likely to

be tubercular in origin and that in them we may expect the clinical picture described in this paper.

Corner believes that milk and the bovine type of tubercle bacilli are the primary factors in the causation of this disease, and when the condition is in an advanced stage and there are many glands in the lymphatic chain Talbot has shown how the absorption of fat may be prevented by the blocking of the lymphatics by these glandular masses.

Three or four pertinent questions arise in the diagnosis and treatment of this class of case.

1. If the history, past and present, and the physical signs are carefully gone over, is there not a symptom-complex or certain more or less distinctive picture by which we can more accurately make the preoperative diagnosis?

2. How can this condition be differentiated from appendicitis?

3. What is the prognosis? With operation? Without operation?

A brief review of the essential facts to be noted in this type of infection is as follows:—

1. The disease is extremely common in infancy and childhood, but by no means confined to this period, being nearly as common in young adults. In fact, the highest percentage favors the years between 6 and 18. It is not uncommon in persons up to 40 years of age. One case in this series was 58 years old, but occurrence at such a late age is extremely rare.

2. Corner's attempt to divide the condition into an adult anatomical type which occurs in the region of the cecum and gives pain in the stage of caseation, usually diagnosed as appendicitis without palpable tumor, and a type peculiar to young children in which there are palpable glands usually in the free mesenteric edge of the small intestine, we believe should not be made, as numerous cases in this series and those reported by other writers show no difference in type assignable to age; both types being found in the very young and in the adult.

3. Two clinical types, however, are noticeable:

(a) Distinctly palpable masses of glands accompanied by none or only vague abdominal symptoms.

(b) Cases with alarming abdominal symptoms and signs developing suddenly when there are no palpable glands demonstrable.

It is a notable fact that unless the glands are sufficiently enlarged to form palpable masses there are probably no symptoms present which would suggest a tubercular infection, while when there are pronounced symptoms such as diarrhea, night sweats, temperature, etc., it is probable that there are other tubercular foci elsewhere in the body which are causing this train of symptoms and that they cannot be referable alone to the mesenteric involvement. On the other hand, primary mesenteric glandular tuberculosis may be the only underlying cause of a train of sudden acute right lower quadrant

symptoms demanding surgical relief. For this reason the diagnosis is often difficult or impossible.

Symptoms:—

(a) There may be none; even in the presence of palpable masses of gland.

(b) The condition may be discovered only at operation for some other condition; the glands being too small for palpation through the abdominal wall.

(c) Trivial symptoms such as fleeting and not severe right-sided or general abdominal pain with or without disturbance of digestion and bowel regularity, the general health being good or the patient being of the pale rather "sickly" type.

(d) More or less constant fairly well localized abdominal pain with generally a "soreness" referable to the region of the cecum; the most likely situation of the growth. Physical examination may or may not show the presence of resistance or an ill-defined glandular mass.

(e) Sudden (or gradual) onset of general, then localized abdominal pain confined to the right lower quadrant, rise in temperature up to 99, 100 or 101°, nausea and vomiting, constipation or diarrhea, and on physical examination, acute localized tenderness with spasm and resistance, a white count up to 12 or 15 thousand, and a very sick appearance. There may be distention, complete obstipation, severe vomiting and all the signs of obstruction. (This latter, however, is rarely present unless there is a real obstruction, which is due to extension of the tubercular process matting and binding intestines together.)

That the process is sometimes a fulminating one and that the glandular enlargement sometimes precedes a general tubercular peritonitis and may be cured by operation is shown in the following case of this series.

L. L. H., 9 years old, had lived in a country district, had had much out-of-doors' life, but had never been very robust. He was pale but considered healthy. He had had no previous illness. He was taken suddenly 48 hours before seen by the writer with sudden general abdominal pain, nausea and a few watery bowel movements followed by constipation. Castor oil, given by the local doctor, was vomited; the patient looked sick and had a slight fever. As no improvement took place in 48 hours he was transferred to the writer's care.

P. E. showed distended abdomen, general abdominal tenderness, no masses. Temp. 101°, W. C. 9000. A diagnosis of intestinal obstruction, probably due to intussusception, was made. At operation the lower ileum was found adherent to the side of the ascending colon near the cecum, and to a large ulcerated T.B. gland in the mesentery. Several smaller glands were found in the adjacent mesentery. Exploration of the rest of the abdomen failed to show any other pathology. The peritoneum was smooth and not injected. The convalescence progressed satisfactorily but slowly till the 11th day, when signs of further intestinal obstruction developed and the abdomen was again opened

and a few fresh adhesions freed, and to the great surprise of the operator and his assistants the whole peritoneum, both parietal and visceral, was found to be thickly studded with tubercles, several of which were excised and reported to be tuberculous. The convalescence from that time was uneventful. The patient has been seen four times since at intervals of a year apart, has gained in weight, there are no masses or fluid present. This case is of unusual interest in that the development of the tubercles took place so rapidly after the first operation. The patient has at present a hernia in scar, for which it is hoped he will seek operation later. The final condition of the abdomen can then be recorded.

It is evident, therefore, that we have in *tabes mesenterica* a condition which, like appendicitis, the lesion with which it is most often confused, has a variety of symptoms and signs, none of them distinctive in themselves and from the analysis of which we are seldom able to make an exact preoperative diagnosis.

If the patient is pale and "sickly," has had more or less localized right-sided abdominal pain and has a low fever and white count with palpable glands and is a child or young adult, the diagnosis is easy, the picture being clear. But in the absence of palpable glands and with an acute onset with high fever and white count the condition is naturally diagnosed as appendicitis.

With the idea of perhaps shedding some light on the question, especially of symptomatology and past history in these cases all the autopsy records of the Massachusetts General Hospital have been gone over and these cases analyzed from a pathological as well as from a clinical point of view.

In 65 cases in which one or more retroperitoneal or mesenteric obsolete or active tubercular glands were found at autopsy, the clinical record of each case was looked up, especially from the point of view of past history, previous health, and attacks of abdominal pain. And in so far as hospital records show or are of value in determining this point, none of these 65 cases had anything in their past history which could be interpreted as referable to the presence of tuberculous retro-peritoneal or mesenteric glands.

These cases of course do not include those cases operated on for this condition, but only cases in which a diagnosis was *not* made before death, and one or more glands were found incidental to other conditions at autopsy. This seems to indicate that very many people harbor obsolete or quiescent tubercular glands of even considerable size without ever having any symptoms referable to them.

This is well illustrated by the fact that in 4 cases the glands were adherent to the intestines, in 3 there was ulceration present, in 5 there were great numbers of glands and in 5 masses the size of the fist or larger were present, and yet no symptoms resulted.

These masses are variously described by the pathologist as follows: Obsolete tubercular mesenteric glands, large masses of obsolete tuber-

cular glands adherent to wall of the intestine, many retroperitoneal glands along the wall of the aorta, mass size of an egg caseous and calcareous, soft tubercular mesenteric glands, adherent tubercular nodes in the mesentery, retroperitoneal and in the omentum, soft and caseous glands, slightly ulcerated at base, large fibroid calcareous mass near the cecal valve; and yet no symptoms could be found in the past or present history referable to these masses, the patients dying of such conditions as broken compensation, pneumonia, typhoid, brain abscess, septicemia, glioma of brain, aortic regurgitation, pyonephrosis, appendicitis, empyema, etc.

It is fortunate that there is never much question as to the treatment in the acute cases. The condition is an acute adominal one and demands surgical relief.

Adhesions may be found with true ileus, ulcerated or necrotic glandular masses may demand removal or drainage, or large masses of glands producing pain may also demand removal. This latter circumstance is well illustrated by a case reported by Newbott in which appendicitis was diagnosed but only a few calcareous glands found in the mesentery of the lower ileum at operation. These were not disturbed, the appendix only being removed. After operation the patient complained of the same pain as before operation; six months later the abdomen was reopened and the glands removed, with prompt relief of symptoms.

The indication seems, therefore, to be for the removal, in the absence of other pathology, of plainly palpable glands which evidently cause symptoms.

In view of the fact that cases of tubercular mesenteric adenitis get well from the mere opening of the abdomen, as tubercular peritonitis cases recover after the same procedure, and that this is the testimony of many surgeons seeing numbers of these cases, it seems reasonable to state that when there is no indication for drainage and the masses do not readily lend themselves to enucleation, good results may be expected from non-interference and proper after-care.

The much mooted question of why cases of tubercular peritonitis so often recover after simple exploratory laparotomy, seems to find its answer in this type of case. We have learned the pathology by our exploratory operation. The patient is then put under the best hygienic conditions to combat his tubercular tendency, he has proper care, his symptom responds to treatment and he overcomes an infection which in many people lies dormant for years without causing symptoms at all. It is not the fact that the abdomen has been opened to fresh air or sunlight that effects a cure, but the fact that the patient from then on has proper care, based on an accurate diagnosis.

An analysis of 30 cases operated on at the Massachusetts General Hospital for some more or less acute abdominal condition, and in which

definite mesenteric or retroperitoneal glands were found at operation, show some points of value.

There were only 3 cases in which the glands were retroperitoneal, the mesentery about the cecum being the common situation.

It is interesting to note and pertinent to the purpose of this paper that in only 3 of these 30 cases was the diagnosis of *tabes mesenterica* made previous to operation.

Other preoperative diagnoses were: appendicitis 10 cases, ileus 3 cases, abdominal tumor 4 cases, pelvic 3 cases, while in the remaining 7 cases the record does not state what diagnosis was made, but as symptoms and physical examinations were described it is evident that the appendix was the organ suspected. In the 30 cases the tuberculous glands were found to be undoubtedly the cause of the symptoms complained of in 17, or a little over half of the cases; in 4 cases it was an open question as to whether they alone could have caused the symptoms, although it was probable, because of their enlarged condition, that they must have been a contributing factor; while in the remaining 9 cases they were small in size and were undoubtedly only secondary to other coincident and more pronounced lesions.

When we try to gather information which will aid in making a correct preoperative diagnosis we are not greatly helped, for only symptoms commonly complained of by those suffering from chronic or recurrent appendicitis are obtainable. For instance, 13 cases had previous similar attacks; of these 8 had general abdominal pain, while 13 (or all the cases) had localized pain either in the previous or present attack.

Of course the physical sign which would be of most value in making a differential diagnosis would be the presence of palpable masses. In 12 cases such masses were demonstrable before operation and in 3 others were discovered when the abdominal wall was relaxed under ether before operation. In 12 cases the history definitely states that no masses were to be palpated. It is here of interest to note that in spite of the fact that masses were palpable in these 12 cases, yet the diagnosis of *tabes mesenterica* was made in only 3. The masses generally being diagnosed as abdominal tumor in 4 cases, appendix abscess, pus tubes and in one case floating kidney. This fact certainly shows that unless distinct chains of glands are to be felt, the history is not distinctive enough to suggest a condition of *tabes* in preference to some more common condition.

The rapidity with which such a process may develop is illustrated by a case in which an appendectomy was done in 1910 and no glands were noticed, although the abdomen was thoroughly explored in routine. In 1913 the case was operated for acute intestinal obstruction and a mass of matted tubercular glands found binding the intestines together. The case recovered. The recurrence of other extra-abdom-

inal tubercular glands coincident with the mesenteric glands seems to be rare. In two cases of this series, glands were present in the neck and groins.

In no case did the white blood count exceed 15,000 except in one in which there was a coincident appendicitis and pelvic abscess. We can, therefore, expect little aid in diagnosis from the blood count.

Operative methods employed have been as follows: Exploratory laparotomy only, recovery one case; 7 cases were curetted and drained; in four cases the masses were too extensive for any operative removal. In two cases the glands were shelled out. The remaining glands were too small or inaccessible or considered too far removed as a cause of symptoms to warrant attempts at removal.

The mortality in this series was 2 cases, or 15%, both cases dying from postoperative pneumonia and not as a result of extension of the process or general miliary tuberculosis.

Two cases were discharged from the hospital with a sinus, but others which were opened and drained, curetted or swabbed out with iodine, completely healed and now show no sinus. In these 30 cases, five have been complete recoveries. In four there is some mass still present, but the patients have no symptoms. Two cases have had similar attacks since operation but consider themselves well. The remaining cases have failed to report up to the present time.

SUMMARY AND CONCLUSIONS.

1. *Tabes mesenterica* is often a primary disease with sometimes a fairly distinct clinical history and signs. It most often simulates acute appendicitis, and when in this stage should demand surgical intervention.

2. In the absence of palpable glands, however, it is impossible to make a correct preoperative diagnosis in many cases, there being no symptom-complex distinctive enough of this condition.

3. A great many people harbor tubercular mesenteric glands in various stages of activity without symptoms.

4. The disease has two clinical types: (a) a slowly progressing one, generally with palpable glands; (b) an acute fulminating type, most often simulating and impossible generally to differentiate from appendicitis.

5. The prognosis in the subacute stage is good without operation. In the acute stage exploratory laparotomy should be done, but the glands not removed unless there are definite indications either from adhesions, ulceration or size of mass producing pain or mechanical obstruction.

6. In children and young adults with a history of right-sided abdominal pain, with or without palpable masses, *tabes mesenterica* should always be considered as a possibility.

I wish here to express my thanks to the surgical staff of the Massachusetts General Hospital

for permission to analyze the records of cases operated on in looking up this subject.

A LOCALIZED, SUBACUTE FORM OF BRONCHIO-PNEUMONIA.

BY RALPH C. LARRABEE, M.D., BOSTON.

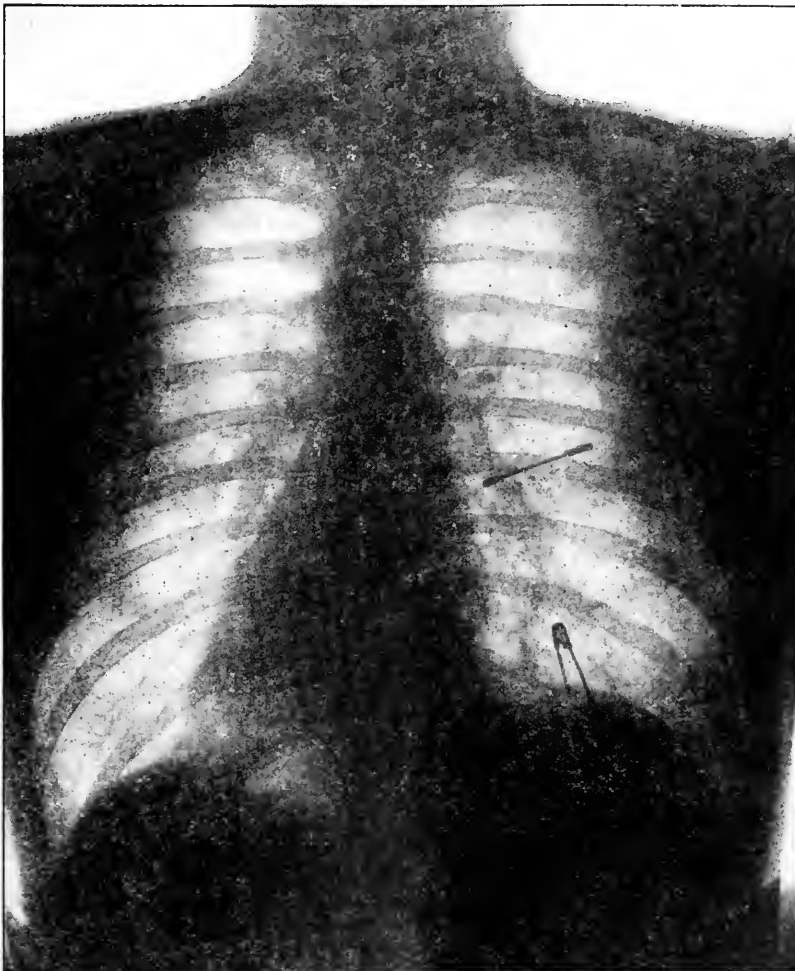

W. J. P., a male nurse, age 46, was admitted to the City Hospital on August 4, 1913. He had always been well. About ten or fifteen days before admission he began to cough; this symptom being at first mild, and later only moderately severe. The expectoration was abundant and was stated to have shown slight streaking with blood before admission. He had no pain and was just about sick

enough to stay in bed. He stated that, before entering the hospital, his temperature had been as high as 102.2°, but the highest record thereafter was 100°. It ran a low, irregular course and did not remain normal till after the thirteenth day in the hospital, its total duration being three or four weeks. There was nothing like a crisis.

In the lower half of the right back there were numerous, coarse, moist râles. At first there was no dulness and no change in the voice or breathing sounds. Later the râles became finer, and there was more or less dulness and diminution of sounds. Consolidation was never recognizable by physical examination.

The leucocytes were 21,200 on admission, later counts being 19,800, 10,000, 9,600, 11,500 and 15,200, the two latter being obtained after convalescence appeared to be well under way. The x-ray showed a slight, but definite shadow in the lower, outer portion of the right lung, occupying in the plate merely the corner of the lung outside the swell of the diaphragm. There was also some increase in the intensity of the markings, usually considered to be due to the blood vessels or bronchi.

The sputum was examined for influenza bacilli and several times for tubercle bacilli, always with negative results.

W. P. Age 46.

Broncho-pneumonia at right base. The normal markings in the lung are somewhat exaggerated. There is a distinct shadow just outside the swell of the diaphragm.

The patient improved very slowly. The physical signs cleared up gradually, examination being recorded as negative about one month after admission. The total duration of illness, from onset to discharge from the hospital was 58 days.

This case is reported at length as it represents a type which, though very common, has received little notice in medical literature. I have seen a good many such cases in the past few years. This paper is based on a study of seventeen seen in the wards of the Boston City Hospital and in private practice. Perhaps as many more were seen in the out-patient department of the hospital, but these were not included, nor were cases seen but once in private practice or in consultation. The condition may be described briefly as a pulmonary infection, localized in the lower portion of one lung and characterized clinically by lack of definite consolidation, mild course and long duration. Riesman,¹ in 1913, described a series of cases of "A Lobar Form of Broncho-Pneumonia of Long Duration, Occurring in Children and Young Adults." His description corresponds very closely to that of my cases.

About two-thirds of my cases were in males. Their ages varied from ten to seventy-five. In this respect they differ somewhat from Riesman's, which were mostly children and adolescents. Perhaps this is because of the different character of the material making up our respective clinics. My cases occurred at all seasons of the year. I have seen many in the summer. This is in contrast to lobar pneumonia, which is very much more prevalent in winter and early spring.

The onset is usually gradual. Only one of the cases collected in preparing this paper had an initial chill. One other had a chill with a temperature of 102° F., occurring after a "cold" of a week's duration. The notes usually state that the patient "began to cough" or "had a cold." Medical care is usually called for only after the patient has been ill for several days or even two or three weeks. Not uncommonly the patient seeks relief only because the cough and malaise have not cleared up as they usually do after a cold.

The most striking symptom is cough, often severe, bothersome and persistent. Pain was present in but two of my cases. More or less fever is generally present at some stage, though I have seen several cases in which a fairly complete record showed a normal temperature throughout. It may be as high as 103° for a day or two, but the common finding is a low, irregular curve, the daily maximum being 101 or 102°. It varies a good deal in duration, sometimes lasting several weeks, sometimes but a day or two. Recrudescences are common. As might be expected in such curves, the termination is indefinite. I have, however, seen two cases in which the fever was high enough and the termination abrupt enough to constitute a real crisis.

But the end of the fever is by no means the end of the disease. Signs and symptoms may persist for weeks or even months after defervescence.

The physical signs are so definite that the nature of the process can generally be recognized at the first examination. One caution is, however, in order. The nature and distribution of the signs are such that unless one is in the habit of making a thorough examination in every office patient or out-patient, with the shirt and corsets removed and the whole chest exposed, they will often be overlooked. Percussion generally shows dullness, low down in one back or axilla, often so slight as to be discoverable only on careful comparison of the two sides. This impairment of resonance usually increases as time goes on, and it may persist after other signs have disappeared. Changes in the voice and breathing are relatively unimportant. The sounds may be increased in intensity at first, and may have to a slight degree the bronchial character that suggests consolidation. Frank consolidation does not occur, or if it does, it is of very limited extent and of very short duration. Later on, both sounds and fremitus are more apt to be decreased.

The most characteristic feature is the râles. They are generally very numerous and easily heard if one listens at the right spot,—most frequently the extreme base. They are very persistent. In character they are coarse or medium, crackling, moist or sticky. With all due allowance for personal variations in the use of descriptive terms applying to râles, I cannot agree with Riesman that they are "consonating"—I think this is very unusual. All these signs are characteristically localized in the lower back or axilla on one side. There may be, for a short time, a few râles at the opposite base or scattered over the lungs, but the most striking feature is the persistent presence of a burst of moist râles at one base.

Satisfactory x-ray plates were obtained in six cases. In two perfectly typical ones the results were negative. In the others definite shadows were present over areas corresponding to the physical signs. The shadows observed have been less intense than in typical lobar pneumonia and even less sharply circumscribed. They have not, as a rule, corresponded in extent with a whole lobe, but have been limited, like the signs, to the lower portion of one lower lobe.

The sputum varies in amount from very slight to very abundant. Blood was present in but two of my seventeen cases,—once for a few days at the onset and once as rare and slight streaking, also in the early days. Tubercle bacilli were sought for in most cases, often repeatedly. Of course no case is included in which the findings were positive.

The leucocytes were counted in thirteen cases. In four the maximum figure was under 10,000, in one between 10,000 and 15,000, in two between 15,000 and 20,000, in four between 20,000 and

25,000, and in two over 25,000. Thus, in the majority of cases there was a leucocytosis corresponding to that of mild lobar pneumonia. In several instances the persistence of the leucocytosis was very striking, it having lasted well into convalescence, after the symptoms and signs had well-nigh disappeared. Persistent leucocytosis, then, is a striking feature.

Blood pressure observations were made in most cases, without striking results except in one instance. This was a man of fifty-eight, whose urine showed albumen and casts for a few days during the height of the disease. The systolic pressure was persistently low—70 to 75 millimeters of mercury. During convalescence it gradually rose, but as late as two months after the onset, long after he had left the hospital, it was recorded as 100.

The duration of cases of this type is indefinite and variable. In my longest case, a boy of ten, localized râles persisted for eight months, and after fourteen months' dulness was still present. In several instances the signs cleared up in a few days. It is not infrequent for the cough and râles to last for six weeks, and dulness with an occasional crackle as much longer.

Diagnosis depends upon the recognition of a localized infection of the lung, physically characterized by slight dulness and numerous moist râles, without frank consolidation, running a mild but protracted course. It may be differentiated from lobar pneumonia by the milder but more persistent course, the low fever, the lack of sudden onset and critical termination and especially by the absence of frank consolidation. Bronchopneumonia of the ordinary sort is usually secondary to other diseases, is commonest in children, is apt to be more severe and is typically bilateral in its distribution. Bronchitis is seldom persistently limited to one lobe, will rarely be accompanied by marked leucocytosis, and will not show dulness to percussion nor changes in the shadow cast by the lung parenchyma on the x-ray plate.

The question of tuberculosis naturally often arises in these cases, particularly when cough, debility and perhaps some loss of weight have persisted for weeks. One of my first cases was recommended to a sanatorium for tuberculosis by one of our best specialists and was accepted by the admitting physician. I found only a burst of râles at one base, and advised delay in the institution of sanatorium treatment—a somewhat risky bit of advice. Under reasonable care her signs and symptoms promptly cleared up, but it was long before she recovered from the emotional shock of that dreaded word, "tuberculosis." It is best to delay the use of that word where symptoms have existed but a few weeks and the signs consist of dulness and a burst of râles at one base.

The prognosis is almost invariably good. In only one of my cases, a feeble old gentleman with advanced arteriosclerosis, was there a moment's

anxiety as to the immediate outlook. The disease is usually very mild. Most cases will be confined to bed for at least a few days, some not at all, some will keep at work. It is, however, best not to state the probable duration. Even a strong young man, with slight symptoms and signs, may be incapacitated for weeks.

No form of treatment is likely to produce any astonishing immediate results. The patient should be confined to the bed as long as fever persists, with a reasonable margin of safety. Afebrile cases may be simply confined to the house. I have treated a number as office patients, and as hospital out-patients throughout. In reasonable weather they do best out-of-doors, but here, as in everything else, common-sense must temper enthusiasm. The writer does not believe that any acute pulmonary infection should be exposed regardless to the full rigors of a New England winter. Of course no drug will materially affect the pathologic process; yet sedatives like codeine and expectorants like ammonium chloride will harmlessly lessen the discomforts of a severe cough with scanty tenacious expectoration. In two cases autogenous vaccines were prepared from pneumococci isolated from the patients' sputa. One seemed to be benefited, but of course nothing can be inferred from such a limited experience.

What is the pathology of this condition? It is certainly an infection for it is accompanied by fever and by leucocytosis, and the general picture is obviously that of a bacterial disease. In the cases upon which I have notes, no careful bacterial examinations of the sputum have been made, but observations made in the course of preparing vaccines for two cases have shown a variety of organisms, always including pneumococci. It is distinctly possible that some were influenzal infections. Influenza bacilli were sought for in but one case, and they were not present in that one.

It is not bronchitis, since the presence of dulness, changes in sounds and fremitus, and above all, the x-ray evidence of increased density show involvement of the lung parenchyma. It is not lobar pneumonia, as there is never any evidence of extensive frank consolidation, nor does the clinical course of the disease correspond to that of this condition. Riesman's view that we are dealing with a lobular or catarrhal pneumonia is probably correct. The principal departure from the usual type is that it is confined to one lobe or to a portion of one lobe, and that it runs a milder and frequently a more protracted course.

In one or two cases the patient had cardiac decompensation and the pulmonary condition was apparently an infection of one of the edematous bases. The course, however, apart from the cardiac condition, was not dissimilar to the others except in severity.

In acute infections of the lungs we recognize certain conspicuous types, such as the ordinary forms of broncho- and lobar pneumonia, bron-

chitis and pleurisy. But we often meet with infections due perhaps to the same organisms, which we cannot classify under these headings. In the writer's opinion the class of cases to which this paper has reference constitutes a sufficiently definite type to deserve a pigeon-hole of its own.

THE FIELD FOR LOCAL ANESTHESIA AND OF SPINAL ANESTHESIA IN GENITO-URINARY SURGERY.

BY ARTHUR HALLAM CROSBIE, M.D., BOSTON.

DURING my present service at the Boston Dispensary the importance of local anesthesia has been brought to my attention with such force that I feel that it is worth while to speak of some of its uses. Probably many others here are using it as much, but there may be many like myself who have hitherto neglected its use to the fullest extent in out-patient clinics.

The matter was especially brought to my notice by Dr. Rosenkrantz of Los Angeles who had just returned from three years' study and practice in Germany and Servia. He was shown several cases of epididymotomy that we had done for acute epididymitis. These cases had been done under ether either at the patients' homes or at a hospital. I was deploring the fact that we had many such cases that should be operated upon, but they could not go to a hospital nor could they have it done at home. He suggested doing the operation in the clinic under local anesthesia, although he had not seen it done. I felt that it was too much of an operation for an out-patient clinic. Very soon, however, I operated upon two cases of acute epididymitis, using a 2% solution of novocaine, to which had been added a small amount of adrenaline. The results were so good that now Dr. Augustus Riley and I do even the most acute cases

FIG. 2.—The needle inserted into the inguinal canal.

FIG. 5.—Infiltrating the cord.

under it. We use from 20 to 30 c.c. of a .5% to 2% solution of novocaine to which are added from 3 to 6 drops of adrenal solution 1-1000. We use usually 1% novocaine as it seems to give just as good anesthesia as 2%, especially when used with adrenal solution.

The method we use is much the same as Braun, in his recent book on local anesthesia, advocates for any operation on the testes. The best syringe is a 10 c.c. glass syringe with a two-inch needle. The first step is to infiltrate the cord. This is done by grasping the cord, at the point where it emerges from the external ring, between the thumb and forefinger of the left hand. From 5 to 10 c.c. of solution is injected in all

directions into the cord in order to be sure to block all the nerves in the cord. It is well also to inject a little into the inguinal canal itself. This is done to get complete blocking. The needle is then pushed downward along the cord to the region of the globus major and a little more solution injected. The scrotum is then circum-injected, on the side to be operated on, all the way to the perineum. This injection is made where the scrotal skin merges with the skin of the thigh. Even though the operation be unilateral, Braun recommends anesthetizing the scrotal skin all the way around, the same as one would for a double operation. We have not found this necessary as we get complete anesthesia by injecting the one side. Finally, a little novocaine is injected into the skin along the line of incision. In order to get perfect anesthesia it is well to wait ten or fifteen minutes. With the anesthesia thus obtained any operation may be done on the scrotum or testicle without pain. We have found that patients having an epididymotomy done under this form of anesthesia are able to walk out after the operation in comparative comfort. Such patients report back to the clinic for dressings.

The above method is suitable for epididymotomies, resecting spermatoceles and hydroceles. It would work well for varicoceles, but we do not use it in the out-patient clinic because of the danger of local bleeding. A patient after a varicocele operation should remain in bed for a few days.

FIG. 5.—The line for injection in circumcision.

A modification of this form of anesthesia works excellently for circumcision. The method is much the same, a ring is infiltrated about the base of the penis close to the pubes. A little novocain is injected into the corpora cavernosa as well. This gives complete anesthesia of the whole penis, so that any operation, such as circumcision, cutting strictures of the anterior urethra, operations for phimosis and paraphimosis or even amputation of the penis can be done without pain. I find this method of especial advantage in doing circumcision, because in the old way of infiltrating the prepuce I was seldom able to get complete anesthesia and the infiltration rendered the parts worked upon very edematous, which was a great disadvantage.

For anesthetizing the urethra for cystoscopic work or cutting anterior strictures we have been using a 4% solution of alypin with very good results. We use as much as necessary to get complete anesthesia and have had no toxic symptoms from its use. It is injected into the urethra with an Ultzmann syringe and held in from five to ten minutes. For cutting anterior strictures some people use the alypin made up with a soluble lubricant, which is injected into the urethra with a urethral syringe. I can see no especial advantage to this method.

Braun recommends doing perineal section for prostatectomy and for external urethrotomies under local anesthesia, but most men in this country prefer ether or spinal anesthesia for such work.

Novocain is an excellent anesthetic for doing suprapubic cystotomies, especially in old people, to whom you prefer not to give ether. The method is very simple. With a ten c.c. syringe the skin, subcutaneous tissues, muscle and pre-vesical space are infiltrated with a 1% or 2% solution of novocain and suprarenin. After waiting the usual length of time for the anesthetic to take effect, an incision is made down to the bladder wall. It is well then to inject a little 2% novocain into the bladder wall itself. The bladder can then be opened and drained without pain, provided you do not make traction on the bladder wall or press upon it. Traction and pressure on the bladder wall cause pain, even after the use of novocaine.

The anesthetic of choice for prostatectomy, either suprapubic or perineal, especially in feeble old men is spinal. The solution of choice is tropeocaine.

Spinal anesthesia when properly given should produce satisfactory anesthesia for from three quarters of an hour to an hour and a half. In using spinal anesthesia for patients that are put into the lithotomy position care must be taken not to put them up into position for fifteen or twenty minutes, on account of the danger of producing too high an anesthesia.

The advantages of spinal anesthesia in these cases are many. First and foremost stand the lack of shock due to nerve blocking and the lack of ill effects on the kidneys.

The genito-urinary surgeon more than any other surgeon has to deal constantly with kidneys that are below par. An old man with long standing prostatic obstruction and constantly over-distended bladder has kidneys which have been weakened and their excreting powers lessened by the back pressure. The surgeon has to conserve the ability which such kidneys have left and must seek to improve it as soon as possible.

Ether does irritate the kidneys and spinal anesthesia does not. That in itself is reason enough for its use. In many of these cases it is of the utmost advantage to push water into them at the earliest possible moment to the limit in order to stimulate the kidneys to secrete prop-

erly. After ether it frequently happens that there is nausea and vomiting for several hours and fluid has to be introduced under the pectoral muscles or else let the patient go for several hours without enough fluid, thereby inviting the kidneys to shut down and produce uremia. Using spinal anesthesia, water can be started at once, even during the operation. There is no doubt that many poor risks are now saved by using spinal anesthesia who would have been lost by the use of ether.

The disadvantages of spinal anesthesia are its toxic elements and the fact that it is sometimes difficult to use in neurotic highstrung people. The toxic dangers have been pretty well eliminated by the perfection of the drug used. Highstrung patients are often helped by injections of morphine given some time before the operation.

I have not undertaken to describe the method of giving spinal anesthesia, as it should be done by a specialist and is not a part of the surgeon's work.

There are many more genito-urinary operations that can be done under local anesthesia, in fact most all such operations can, although in kidney work it is not very satisfactory except where it is necessary only to open a perinephric abscess or something of that sort in a patient who is too sick for ether.

In this paper I have attempted to show especially what can be done with local anesthesia in a genito-urinary out-patient clinic.

Medical Progress.

REPORT OF PROGRESS IN MENTAL DISEASES.

(Concluded from page 226.)

PART II.

BY HENRY R. STEDMAN, M.D., BROOKLINE, MASS.

NERVOUS AND MENTAL DISTURBANCES FOLLOWING CASTRATION IN WOMEN.

FROM an analysis of 112 cases Gordon¹¹ concludes that (1) Removal of the reproductive organs in women causes disturbances in the domain of the nervous system. These disturbances are of a purely functional nature. (2) The disturbances are somatic and psychic. (3) The psychic manifestations, while individually they belong to any of the varieties of psychoneuroses, nevertheless in their ensemble do not constitute any of the well-established classical forms of psychasthenia. (4) True insanities are not observed. (5) The generally observed symptoms are: restlessness with a tendency to move from place to place; difficulty of self-control; dissatis-

faction with all and everything; difficulty of finding contentment in one's own efforts; want of interest in all absorbing subjects and objects; indifference, indolence and pessimism. Sometimes there are outbreaks of anger with a tendency to attack. Among other symptoms may be mentioned: insomnia, gastro-intestinal disturbances of a functional nature, headache, vague pains or paresthesias, also occasionally glycosuria; tendency to obesity is also observed in some patients. (6) While the psychic manifestations are sometimes of a very disturbing nature, nevertheless they do not present the characteristics of genuine psychoses. For example, indifference and want of interest in surroundings lack the depth of those of melancholia or of dementia. Restlessness, which is so frequently observed here, lacks the characteristic features of exaltation in the motor sphere observed in cases of mania. As mentioned above, while individual symptoms of his cases resembled those of psychoses, the entire picture of each lacked the depth and definiteness of any of the forms of insanity. Some of his patients had to be removed from their surroundings and isolated, not because they were insane in the proper sense of the term, but because of inconveniences caused by them to others. Besides, the subsequent histories of the last category of patients as well as of any other patient of his entire series proved at no time the existence or eventual development of true psychoses. On the other hand, it is striking that the morbid phenomena persist with remarkable obstinacy; at times they become more accentuated, at others some improvement is noticeable, but then it is only temporary. Some of his patients have been under observation during a period of ten years and the condition still persists unaltered. (7) Individuals who presented various manifestations of psychoneuroses before they fell into the hands of surgeons, had their psychic phenomena decidedly aggravated after the uteri and ovaries or only the ovaries were removed. (8) As in the removed organs healthy portions of tissue were invariably found, it is to be supposed that the removal of the latter is in some relation to the morbid phenomena observed after the operations. (9) The logical conclusion seems to be that one must be very cautious in advising operative procedures on the generative organs and the tendency should be to preserve as much as possible of any amount of normal tissue found in the uterus or ovaries. (10) No operation should be advised on healthy organs if a woman complains of vague disturbances.

NERVOUS AND MENTAL AFFECTIONS IN THE FIELD.

Weygant¹² says that, contrary to the practice under other conditions, the aim should be to hurry the patient away at once, stupefy him with a narcotic if necessary, and also use force if unavoidable; even a strait-jacket may be needed.

The main thing is to get him out of the battlefield environment at the earliest possible moment, and the less he remembers of the journey the better. There is no special war psychosis, but war is very liable to fan into flame a latent predisposition to epilepsy, hysteria, slight imbecility and manic-depressive or catatonic attacks, or a syphilitic brain or spinal cord trouble. Prompt removal of those affected is important not only for their own welfare but even more on the account of the effect on other soldiers. A kind of "mass psychosis" is liable to develop in a time of panic, such as occurred at Kirkilisse and Lule Burgas in recent years. He cites figures showing that psychoses developed in 0.54 per thousand of the German troops during the Franco-Prussian war; in 2.7 per thousand of the United States troops in the Cuban war, in 2.6 per thousand in the British during the Boer war; and in 2 per thousand in the Russian troops during the war with Japan, while the records show only 0.33 per thousand among the Bulgarian troops and also in the Servian troops, and 0.097 per thousand among the Grecian troops. He ascribes the difference between the Russian and the Balkan figures to the liquor-drinking among the Russians. He does not offer any explanation, however, for the large numbers among the German expedition corps in Southwest Africa, 4.95 per thousand; including cases of epilepsy and hysteria, 8.28 per thousand of the troops were thus affected.

MENTAL DISORDERS AND PERNICIOUS ANEMIA.

Barrett¹³ has studied clinically the mental disorders of 11 cases of pernicious anemia, and in 9 of these a histologic study of the brain was made. The symptomatology of these cases showed considerable variety. Two were cases of epilepsy, 2 were not to be differentiated from dementia precox, 1 was a questionable manic-depressive psychosis, and 6 presented a characteristic picture of an asthenic state in which there developed a mental disorder of a paranoid type. It is to these paranoid conditions that this study is particularly devoted.

Brief accounts of 6 cases are given by Barrett. The first 2 of these showed a slight tendency toward delusional elaboration. In the remaining 4 the paranoid features were well developed. The cases, as a whole, have in common an irritability, and a suspiciousness which forms the ground on which develop the delusions of persecution. The content of the delusions is usually influenced by the somatic-neurologic symptoms and the situation in which the patient is placed as a result of these disturbances. In some instances there were auditory hallucinations to which the patient reacted with strong affect. In several cases there was confabulation, which suggested that seen in the Korsakow's syndrome. Comprehension and orientation were usually

clear, except for rare episodes, in which they were slightly disturbed. In two instances the mood was slightly expansive. In a number of instances the course showed remission in the intensity of the physical conditions. Underlying the development of the mental condition in all but one of these cases was a hereditary predisposition. In several instances there was a number of occurrences of mental abnormalities or insanity among the ancestors. In all cases of pernicious anemia with mental disorders studied, hereditary factors were found in the greater number.

The histologic changes in cord and brain as a whole are not of a specific type, but rather those which occur in conditions of chronic intoxication and resemble those found in chronic alcoholism, namely, the occurrence of increased lipid products in cells, glia overgrowth, vessel changes, miliary hemorrhages and intramedullary fibre degeneration. The similarity to a toxic type is further shown in the axonal type of reaction which was found in two instances, a change which has often been noticed in the Korsakow's symptom-complex and various forms of toxic neuritic disorders. As in toxic processes, the vessels are severely affected.

Clinically, Barrett points out there are features in these paranoid cases which resemble closely those seen in chronic and subacute toxic conditions, especially the chronic alcoholic delusional states. These are the occurrence of the suspiciousness and irritability, the development of the delusions of persecution, the auditory hallucinations and occasional memory impairment and confabulation.

INSOMNIA AND SUICIDE.

Under this title Pronger¹⁴ discusses the influence that slight refractive errors have in causing many of the functional nerve troubles, so prevalent in these days. Among these, insomnia has naturally had a prominent place. Slight errors of refraction, although not causing any visual defect, are of great importance in that they give rise to sundry neuroses. Especially, says Pronger, should these slight degrees never be ignored in any case of insomnia, because some error is nearly always present in those cases not associated with organic disease, such as tumor, kidney troubles, and the like, or with persistent pain from any cause. Insomnia is not usually the only symptom, but is generally associated with attacks of great depression, and often with giddiness or headaches. A few illustrations are given by Pronger of what can be done for the relief of insomnia, and also of some of the difficulties that have to be surmounted, particularly the skepticism of the patient as to the possibility of glasses being of use for such a purpose, especially if the sight is good or an oculist has already been seen.

THYROID EXTRACT IN CERTAIN MENTAL DISORDERS.

For many years Goodall¹⁵ has employed thyroid extract in cases of stupor and stupor with melancholia, or of confusional insanity—cases which have certain features in common with myxedematous cases, but until the last two years the failures were more numerous than the successes. He attributes many of those failures to the circumstance that he gave insufficient doses of thyroid. His recent experience entirely justifies those who have insisted on large doses if any benefit is to follow. Thyroid is not only beneficial in acute stupor, or acute dementia, and “confusional” states, but also at a later stage of these conditions and of cases of recent melancholia, when the patient has improved to a certain point and there remained. In these cases administration of thyroid has appeared to complete the process of recovery.

Eleven such patients were treated by this method. They were kept in bed during the whole course of treatment, usually in the open air, on liberal diet, and the temperature, pulse, and respiration were taken throughout twice daily. All had been mentally ill for months before the thyroid treatment was started. The amount of thyroid given varied from 25 to 50 grains a day for five to eight weeks. The pulse-rate was affected in the direction of increase very consistently, whereas the temperature and respiration were affected but slightly, or not at all. Gain of weight during the treatment occurred in two of eleven cases; one showed no change; in all the others a loss was noted, but after cessation of treatment weight was rapidly regained, and in eight instances there was ultimately a gain on the original weight. The results were highly satisfactory, since no less than six patients of eleven became well; and all the others except one, showed a definite improvement, and this one had been deranged for no less than three years when treatment was employed.

In eleven out of twelve cases of epileptic insanity treated with thyroid the number of fits was reduced. The patients were not on any other drug, but were kept in bed on ordinary diet, with in some cases, extras, such as milk and egg. A reduction of weight occurred in all except one. The observation as to the pulse, respiration, and temperature made in connection with the first series of cases apply also to this series. On the basis of these results Goodall kept certain of these patients on 5 grains of thyroid daily for a prolonged period; the patients were up as usual and on their usual diet. A substantial reduction in the number of fits occurred in many of these cases, amounting in some to from 52% to 65%, as a result of a small daily dose of thyroid. No ill-effects were observed.

Lemoine¹⁶ is quite encouraged with the results of thyroid treatment in the twelve cases in which he has given it a thorough trial. These patients were all between 17 and 24. The improvement

persisted for five years in one case, and then there was a return of the former condition. In the other cases the improvement has persisted to date, but the interval since has been shorter. In one case the interval is still too brief for estimation of the outcome.

HYOSCINE IN MENTAL DISORDERS.

Daniel¹⁷ summarizes the important points regarding the use of scopolamine hydrobromide as follows: (1) The continued administration of scopolamine hydrobromide may give rise to characteristic symptoms of chronic poisoning. (2) Weak-minded epileptics appear to have a marked idiosyncrasy for the drug. (3) Careful watch should be kept on all patients taking hyoscine regularly, and undoubtedly the best test for any ill effects is the weighing machine. (4) For acute excitement there is no drug so reliable as hyoscine when given hypodermically, but the doses must not be repeated indefinitely. (5) Lastly, there is no doubt that life may be endangered by hyoscinism.

THE WET PACK IN THE TREATMENT OF INSOMNIA AND MENTAL DISORDERS.

Raynor¹⁸ regards the following classes of cases as the most favorable for its therapeutic employment in asylums: (1) In acute delirious mania, of sthenic type, with continued insomnia. It constantly succeeds in producing sleep when narcotics have failed utterly; also, in mania of sthenic and active type. (2) In insomnia accompanying mental disorder, with associated toxic conditions, whether of melancholic or of maniacal type. Climacteric and gouty conditions, alcoholic and drug habit cases are specially benefited. He shows that its first effect is the production of a cold state, with shivering and a falling temperature. This is followed quickly by the stage of reaction, in which the temperature rises and there is profuse sweating due to dilatation of the cutaneous vessels, with subsequent sleep. There is probably considerable elimination of toxins in the sweat. He lays stress on the point that as soon as the temperature reaches the normal the coverings should be diminished, as it is not desirable that pyrexia should be produced, and he adds other practical points to be observed. This mode of treatment, which is certainly of great service in the treatment of some forms of mental disorder, of insomnia, and of many bodily disorders which are found in the insane as well as in the sane, he regards as especially advantageous for institutions for the insane. He adds that the vanished employment of wet packing in asylums [in England] is almost certainly due to its being classed as a form of restraint. The regulation of 1872 enforcing the record of wet packing was certainly not intended to produce this result, but only to check its abuse as a method of veiled mechanical re-

straint. The lunacy commission, he remarks, has been always most punctilious in avoiding any interference with legitimate therapeutical methods, yet the use of the dry and wet pack is still considered as a method of restraint in their revised regulations of 1913. These regulations demand still further consideration and it may be hoped that, whilst preventing the abuse of wet packing, they may be so framed as to encourage its employment as one of the most important and valuable means of treatment of the insane.

Book Reviews.

Case Histories in Obstetrics. Groups of Cases Illustrating the Fundamental Problems Which Arise in Obstetrics. By ROBERT L. DE-NORMANDIE, A.B., M.D.; Assistant in Obstetrics, Harvard Medical School; Physician to Out-Patients, Boston Lying-in Hospital; Assistant in Gynecology, Boston Dispensary.

This, on the whole, very excellent volume is a good example of both the advantages and the disadvantages of the case history system of constructing a text-book or book of reference. The cases are given in great detail, and their detailed recital covers not merely the feature in the case which it is especially intended to illustrate, but the case as a whole in all its features. Each case thus assumes a strong verisimilitude to actual experience and carries many lessons beside that which is its especial function in the book. To one who knows the persistence with which incidental lessons often linger in the memory, this is a very valuable characteristic. The book reflects throughout the author's wide experience in direct personal contact with students. The simple lucid style and the wealth of practical detail should make it of great value, not only to the advanced student or inexperienced practitioner, but to all the many physicians who have been obliged to pick up their practical obstetrics after receiving nothing but the routine school training. Such men are usually for many years in a position to profit highly by such practical hints as those with which this book abounds. It is well arranged, the table of contents is excellent, the summaries of each subject are clear and practical, and though the index does not appear very full it should be easy of use as a work of reference when its possessor desires to look up a single subject, but considered as a work of

reference it has the defects of its qualities. The method adopted necessarily makes the discussion of each subject discursive and complicated with irrelevant matter. With sufficient time to read and absorb the subject under review, as given in the cases and summary, the inexperienced practitioner will probably get a better knowledge of the points involved than from the briefer descriptions given in the routine text-books, but he will not get it so quickly nor can he expect to find all he wants at any one spot. The book as a whole furnishes an interesting and surprisingly practical picture of how a careful and thoroughly modern obstetrician conducts his work in all or most of its phases.

Local and Regional Anesthesia. With Chapters on Spinal, Epidural, Paravertebral, and Parasacral Analgesia, and on Other Applications of Local and Regional Anesthesia to the Surgery of the Eye, Ear, Nose and Throat, and to Dental Practice. By CARROLL W. ALLEN, M.D., Instructor in Clinical Surgery at the Tulane University of Louisiana, New Orleans; Lecturer and Instructor in Genito-Urinary and Rectal Diseases at the New Orleans Polyclinic; Visiting Surgeon to the Charity Hospital. With an Introduction by RUDOLPH MATAS, M.D., Professor of General and Clinical Surgery at the Tulane University of Louisiana, New Orleans, etc. Illustrated. Philadelphia and London: W. B. Saunders Company. 1914.

This is a well-printed book of 600 pages covering every portion of the field of local anesthesia. Under this head, as is apparent from the title, Dr. Allen includes chapters on spinal and sacral anesthesia.

This is the book of an enthusiast, who has made much practical use of the methods he describes, and has covered the literature upon the subject in a most extraordinary manner. It is unfortunate indeed that this extensive bibliography is eliminated from the book, even for the excellent reason of avoiding undue bulk. The author has been successively a student, assistant and associate of that brilliant, untiring and original surgeon, Matas, of New Orleans, who nearly two decades ago planned and actually began a book on this subject. It will be somewhat of a surprise to a good many young surgeons to discover that Matas was one of the greatest and earliest investigators of local anesthesia in this country. His name has usually been associated with entirely different branches of surgery. His introduction is interesting and contains a brief summary of the various and unusual procedures which he carried out in those early years. Dr. Allen most enthusiastically credits his teacher with not a few of the great advances made in the early days of local anesthesia.

The Myth of the Birth of the Hero. By DR. OTTO RANK. Authorized translation by DR. T. ROBBINS, AND DR. SMITH ELY JELLIFFE. *Nervous and Mental Disease Monographs*, No. 18. New York: Nervous and Mental Disease Publishing Company. 1914.

This latest addition to the excellent series of monographs on nervous and mental diseases is a translation of a monograph by one of the followers of Freud, applying his view of the domination of the sexual instinct in infantile psychology, to the development of the myths of various nations. Though unconvincing because of the typical Freudian overuse of symbolism to force everything in the myths into a preconceived idea of the rôle of certain elements in psychological factors, the book is interesting, and the translation reads smoothly.

Psychopathology of Everyday Life. By PROF. SIGMUND FREUD, LL.D. Authorized translation by A. A. Brill. New York: The MacMillan Company. 1914.

The psychologic theories of Freud are extremely interesting to physicians who have to deal with the neuroses, mental diseases, or psychology, though many able men are unable to accept parts of his theories, notably the concept of a psychologic censor, and the all-controlling influence of the sexual instinct in psychology to the exclusion of other instincts, and psychologic states. The extension of these theories to the psychology of everyday life is still more questionable than their application to neurotic symptoms and mental states, but is praiseworthy as showing a widening field of inquiry in physicians who are concerned in the study of the neuroses. In spite of these reservations which the reviewer feels he must make for the guidance of his readers, this book throws much light upon many of the phenomena of everyday mental actions of the normal, as well as of the pathologic mind, and shows exceedingly well how the mental processes of pathologic mental states follow the lines of normal psychologic processes. The translation seems well done, and for the most part reads smoothly.

The Unconscious. *The Fundamentals of Human Personality, Normal and Abnormal.* By MORTON PRINCE, M.D., LL.D. Professor (emeritus) of Diseases of the Nervous System, Tufts College Medical School; Consulting Physician to the Boston City Hospital. New York: The MacMillan Company. 1914.

Dr. Prince has long been known for his numerous and careful studies of abnormal psychology, and this book consists mostly of selected lectures from courses on that subject delivered at

the Tufts College Medical School and at the University of California in 1910, though these have had incorporated in them a large amount of new material, and the subject has been treated more in detail than was practical before students. The book is clearly written, and anyone, even without any special knowledge of psychology or abnormal psychology, should have no difficulty in following the writer in the development of his ideas.

The first lectures take up the theory of memory, and certain of the phenomena connected with it, with illustrations drawn from both the normal and the abnormal. A lecture on neurograms then pleads for a physical basis in the brain as a foundation for memory. The various phenomena of the unconscious and of subconsciousness are then very clearly set forth. The remaining lectures develop the writer's views of the relation of unconscious ideas to the emotions, instincts, sentiments and conflicts, and the origin through these of the abnormal psychologic phenomena which we classify as the various forms of functional nervous disease.

Whether one is ready to accept in full the conclusions of the author as to the origin of these abnormal psychologic states will depend largely upon the reader's knowledge of these states, and of psychologic phenomena, influenced no doubt by the theories held; but no student of these important and exceedingly complicated phenomena can fail to profit from the reading of this book, and rise from it with a clearer idea of the problems to be solved in this field. Those who are not special students of this subject also cannot fail to gain something from its perusal and to be more able to estimate at their true value the articles so often published in popular magazines on certain aspects of these phenomena.

It may not be amiss to call attention to a couple of misprints, the first in the second footnote on page 426, where Dr. Cannon's article should have been credited to the *American Journal of the Medical Sciences*, and another in the last line of the text on page 443, where "cardiac and respiratory disease" should evidently read "distress."

The Clinics of John B. Murphy, M.D. At Mercy Hospital, Chicago. December, 1914. Published bi-monthly. Philadelphia and London: W. B. Saunders Company.

This number contains, besides an index to Volume III, a description of a series of interesting surgical cases; a paper by Dr. C. L. Mix on Hodgkin's Disease; Fracture-Dislocation of the Spine at the Level of the Twelfth Dorsal Vertebra; Appendicitis; Cholecystitis; Sarcoma of Tibia; Arthroplasty for Bony Ankylosis of the Wrists; Tuberculous Epididymitis; Perforating Duodenal Ulcer; Retroperitoneal Sarcoma. This December number does not seem quite up to the previous general average.

THE BLOOD-PRESSURE DURING PREGNANCY.

In the *Journal of the American Medical Association* for January 30 is published the notable contribution to this subject presented by Dr. Franklin S. Newell at the fifth annual meeting of the American Association for the Study and Prevention of Infant Mortality held here in November, which is based on observations on 450 cases from the records of the committee in charge of the pregnancy work carried on by the Women's Municipal League of Boston. He concludes, very properly, that the significance of the rise in blood-pressure noted in a considerable number of women during gestation can be ascertained only by a frequent study of the blood-pressure in a large number of cases, and, in order that definite knowledge on this whole subject may be attained, it is certainly highly desirable that such studies on a large scale should be made. In this series of cases 421 of the 450 patients showed a blood-pressure which at no time was either below 90 or above 130;

in other words, these 421 patients showed what can be properly classed as absolutely normal pressure. Of the 421, 78 at some time during the pregnancy showed a pressure slightly below the normal, ranging somewhere about 90 and 100. In none of these patients, however, was the low blood-pressure persistent, it being observed only on one or two examinations, and in no instance did any uncomfortable symptoms afterward develop in labor which were referable to the low pressure; indicating, therefore, that a temporary low blood-pressure is of no significance during pregnancy. If the pressure remains persistently under 100 it is regarded as fair to assume that the patient's general condition is below par, and steps should be taken to improve it. If the pressure is over 130 the patient should be kept under close observation, even in the absence of other symptoms, and a rising pressure should always receive the most careful attention, as possibly being the initial symptom of an impending toxemia. In the 450 cases the examination of the urine showed albumin persistently or temporarily present in fifty patients. Of these, eleven showed also a blood-pressure of over 130, and every case of toxemia in the series, with the exception of one in which post-partum eclampsia developed in spite of a normal pressure, every case of toxemia occurred among these patients.

Among the conclusions of Newell are the following: In certain cases a rise in blood-pressure was followed by the appearance of albumin in the urine, a combination which has been shown to be a definite indication of the development of toxemia. In only one instance, however, did convulsions occur, the other cases yielding to treatment. Thirty-nine cases showed traces of albumin in the urine, but no change in the blood-pressure. As the urine was not obtained by catheter, the source of the albumin is unknown, but in the majority of the cases it was probably due to contamination of the urine by leucorrheal discharge. To judge from these cases, the presence of a slight amount of albumin, if not accompanied by a rise in blood-pressure, is negligible. All the eleven cases, however, which showed albuminuria with a high blood-pressure were presumably more or less toxemic. Five patients showed a pressure of 140, or over, throughout the period during which they were under observation, but only one of these developed albuminuria at any time during the pregnancy; which would tend to prove that persist-

ent high blood-pressure, in the absence of other signs, is not necessarily a dangerous symptom. Still, it should always arouse suspicion and call for increased watchfulness, whereas, as was shown in other cases in the series, a rise in blood-pressure from a low point is not infrequently followed by the appearance of albumin and the development of symptoms of toxemia, and is more significant than a high pressure throughout. A pressure of 150 has been commonly regarded as the danger line, but a persistent rise of the pressure from a low point, even though it may never reach this arbitrary danger point, calls for most careful attention.

Of great interest in connection with this report is the experience of Dr. D. J. Evans of Montreal, as recorded in a paper on "High Blood-Pressure in the Toxemias of Pregnancy," read before the American Therapeutic Society at its annual meeting in 1912. Evans's material consisted of thirty-eight cases of actual toxemia in which pregnancy was complicated with eclampsia, albuminuria and vomiting of a toxic type, and in twelve of the series the condition was so severe as to call for the induction of premature labor. In eight cases eclamptic convulsions occurred, and among these the highest blood-pressure was 200 and the lowest 140. In most of the cases the pressure was from 170 to 190 immediately before the convulsions. One of the patients had three convulsions, though her blood-pressure did not rise above 150 except at the actual time of a convulsion. Of two patients whose pressure was 200, one had five convulsions, and the other eighteen. There were four cases of severe vomiting; two early in the pregnancy and two near term. In the latter the blood-pressure was 140 in one, and 125 in the other, and in both instances labor was natural. Of the former, one patient, whose blood-pressure was never above 125, recovered from her vomiting and went to term; while in the other case abortion occurred at the sixteenth week and the patient died ten days later. This case was of special interest, as the patient's blood-pressure, usually about 100, never rose above 110; yet she developed retinal hemorrhage, in addition to other signs of grave toxemia. Of the remaining 26 cases, all had albuminuria with toxic symptoms of more or less marked severity. Seven had a blood-pressure of 160, or over; two of them as high as 180. In twelve the pressure was 140, or under, the lowest record being 120.

As a result of his experience Evans reaches

the conclusion that the blood-pressure record is of little value as indicating the degree of toxemia present in cases of severe vomiting, and that further observation would demonstrate that in this class of cases the pressure falls below normal. He has been surprised at the comparatively low reading found in many instances where the symptoms indicated the existence of a very considerable degree of toxemia. In three of his series the induction of labor was imperative although the blood-pressure was 150, or under, while in four cases with a pressure exceeding 150 the toxic symptoms were so slight that the patients were permitted to go to term; when their labors were entirely normal. He is inclined to consider the danger limit as 160, and advises that in cases where, in spite of treatment, the toxic symptoms do not yield and the blood-pressure is maintained at or above this figure, pregnancy should be interrupted. In cases of pregnancy with high blood-pressure without toxic symptoms, a number of which he has met with, he believes there is little occasion for anxiety; but in all cases with renal or hepatic insufficiency the blood-pressure should be carefully watched. A rising pressure, associated with other toxic symptoms, in these cases is indicative of danger. As was suggested in the beginning, there is unquestionably need of further and more extended observation and study regarding the significance of the various phases of the blood-pressure in pregnancy. Thus, in the two series of cases cited, the blood-pressure referred to is presumably the diastolic pressure, and no mention is made of the systolic pressure, which in other conditions has of late assumed a position of very considerable importance.

EUGENIC LEGISLATION.

IN spite of all the optimism of the eugenists it is obvious that, much as it might be desired on scientific grounds, the methods of the stock-farm are inapplicable to human beings. And besides, the study of heredity has convinced almost beyond a doubt that disease tendencies, particularly defects, are transmitted from and by ancestor to progeny; and that it is of far more importance to prevent transmission by this method than to attempt to build up synthet-

ically from "perfect" individuals finer and more ideal products.

The existence of veritable colonies of defectives in many States has persuaded quite a number of the legislative bodies to enact statutes permitting the sterilization under certain conditions and safeguards of the mentally and morally defective populations of public institutions, in the hope that in this way will propagation by these "species" be anticipated, and their line become extinct. The legality of this procedure has, naturally, been attacked—in the defective that it is an interference with the absolute right of person, and in the criminal that it is "cruel and inhuman punishment," and against the constitutional restriction in the eighth amendment. The legal phases of this question are many, and are open, and must be finally decided before this practice can have universal application.

It is not merely jurists or laymen who are opposed to sterilization. Many very prominent scientists have expressed opposition to this practice on the ground that it is unscientific. On the Mendelian elaboration an individual himself defective, when born from the union of a defective and a normal, may yet produce normal offspring, because the dominant determiners in him alone are active, while the recessive or defective ones are dormant or inactive. This is illustrated in hemophilia, where the recessive characteristic causative of the bleeding diathesis is rendered active only when transmitted through a female to her male offspring; and where the bleeder leaves no potent female this constitution is forever inactive, and is finally wiped out because of inactivity. To sterilize the bleeder would be to destroy normal males, as well as the offending females. Reversely, one of two normal mates may have within himself an ancestral recessive defect, dormant in him for the time, but which the union under certain conditions renders active in an offspring. This may give explanation to the presence of a defective in a normal or even otherwise highly developed family.

The opponents of sterilization contend that until something more definite is learned of the method of hereditary transmission, sterilization as a public welfare procedure is not justified. Sterilization can logically only, if at all, be carried out with the distinct mental reservation that there is to be a sacrificing of the lives-to-be of normals in this endeavor to anticipate the inception of defective lives-to-be. And the ques-

tion naturally arises: do these future normal lives-to-be have present value enough for so radical a remedy?

A form of eugenics, negative also, to be sure, that is intended to affect the public in general, is that purposed through legislation requiring all who contemplate marriage to submit certificates of good health as conditions precedent to the issuance of marriage license. The determination and the responsibility for this momentous and often difficult question is thrown entirely on the shoulders of the physician, whether in his private or whether in his public capacity. In effect it is calling upon him to pass on the most organic question in society. His certificates of health will be policies of insurance of immensely greater significance than money risk insurance certificates. They will insure not only against the existence of present patent or present but latent diseases or defects in the contracting parties, but also against subsequent ones arising thereafter, because it will be difficult to determine a causation prior or subsequent to marriage. And yet in so far as venereal diseases are concerned—against which the largest element of this propaganda is aimed—this determination is comparatively simple, only in the very rare instances when the applicants would present themselves for examination during the acute or sub-acute stages. But how many latent gonorrheas escape detection even after the most painstaking examination and even in individuals who will not marry unless declared free from disease? Even recently active syphilis can be made to escape detection by the Wassermann reaction after a period of anti-syphilitic treatment, beside many instances in which the reaction is negative in clinically positive cases not under treatment. Incipient cases of tuberculosis often defy detection, even with the most advanced diagnostic measures, only to bloom out shortly thereafter. Positive cases of insanity will escape the examiner if examined during a lucid interval, or in active cases where the delusions and the like manifestations are studiously concealed. In epilepsy a sufficiently positive diagnosis can never be made between attacks except where the physical and mental deterioration is marked from very profound or very frequent attacks.

Even on the most liberal and on the very broadest construction, how can such a restriction to marriage affect individuals who are themselves admittedly fit, but who present definite taints in their immediate or remote ancestors, and who are

theoretically just as potent to transmit defect as if they themselves were affected? Legislation forbidding them marriage would fail utterly of enforcement because so extreme and because impracticable.

Before such legislation is unreservedly endorsed, physicians must consider that in every case where disease or defect would manifest themselves after marriage, either in the contracting parties or in their offspring, the examining physician would be held under the gravest suspicion—and the integrity and competence of the whole profession might fall into disrepute.

HOSPITAL QUIET ZONES.

At the instance of the Women's Municipal League of Boston an ordinance for the establishment of quiet zones in the vicinity of hospitals was recently drawn up by the Boston Street Commissioners and submitted for approval to the Mayor. The text of the proposed ordinance was as follows:—

"Section 1. The Commissioner of Public Works is hereby authorized and required to conspicuously place and maintain at corners of intersecting streets, avenues, and places on which may be located a hospital or other institution for the care of the sick, a sign or signs displaying the words, 'Hospital Street; Unnecessary Noises Prohibited.'

"Sect. 2. On any street designated as a 'hospital street,' on which such a warning sign as described in the preceding section has been erected, or within one hundred yards of any hospital or other institution for the care of the sick, no person shall make unnecessary or unseemly noises, including the crying out of his wares by a vender or peddler; loud or boisterous speech or conversation by individuals or groups of individuals; the sounding or playing of musical instruments and the sounding of an automobile whistle or horn, other than a reed horn; and no driver of a horse-drawn vehicle shall drive his horse or horses at a speed faster than a walk.

"Sect. 3. Any person guilty of violating the provisions of this ordinance shall be fined not more than \$20 for each offence.

"Sect. 4. This ordinance shall take effect sixty days after its passage."

At a hearing recently held before the commissioners in behalf of this ordinance many causes of disturbance to the sick in hospitals were enumerated by hospital administrators and

other officers. The report of the commissioners to the Mayor regarding the ordinance comments as follows on these complaints and on possible methods of obviating them:—

"The noise of heavy teams rattling through hospital streets is the only one of these things complained of that the board could control. It could do this by making a rule that such teams should be kept out of hospital streets. To this, however, objection was made by team owners and shippers, and not without cause. To give this relief to some hospitals, teaming would have to be diverted from main thoroughfares, and this the transportation interests protest against. The board is of the opinion that so little relief can be given by diverting traffic, it is not worth while to attempt anything in this direction.

"Next to the noise made by heavy teams, that made by the excessive use of the automobile horn or whistle is the worst and the most complained of. It is difficult to say whether it is the statute that is at fault or whether it is the fault of the drivers of motor vehicles, who may be careless as to the use of the horn or indifferent to their surroundings. The automobile statute, it is true, requires operators of motor vehicles to sound a warning at intersections of streets, and they may be punished for not doing so. The same statute, however, undertakes to prohibit the excessive use of the warning signal. There have been many prosecutions for failure to sound the signal, while prosecutions for too much sounding of signals have been rare.

"It would seem that the requirements of the statute would be met if the operator confined his efforts in signalling while near a hospital to the reed horn, which is not so objectionable as some of the other horns in use. To meet this complaint the board has incorporated in the proposed ordinance a provision that only the reed horn shall be used by automobile operators in the vicinity of hospitals.

"In addition to the adoption of some such ordinance as the one proposed, great relief would be given to hospitals if the surrounding streets were paved with some noiseless material. Your Honor has already suggested that this be done. The board heartily concurs with you in this suggestion. With such pavement, and with the requirement that drivers of horse-drawn vehicles shall not drive their horses at a speed faster than a walk in front of hospitals, the sick in these institutions will get as much relief from disturbances in the highways as it is possible to give them.

"It is an unfortunate circumstance that so many of the largest hospitals are located in the busiest of the city's thoroughfares. The board believes, as do most of the good people who give so much of their time and effort to the relief of the sick, in public and private hospitals, that the mere placing of signs calling attention to the fact that the street is a 'hospital street' will

have powerful influence in reducing the noises complained of."

In view of this report and the representations of many persons interested in the passage of this project, it appears that although the original scheme for the establishment of quiet zones about hospitals must be considerably modified, some definite relief from present conditions may be hoped and expected from the provisions of the proposed bill.

THE LOCAL PUBLIC HEALTH OF SUMMER RESORTS.

IN another column of this issue of the JOURNAL we republish the report of a committee on village improvement appointed to deal with the conditions of local public health at a well known New England summer resort. This report illustrates admirably how this community met its responsibilities, so far as health is concerned.

The first outstanding feature of the report is the notable prevalence of typhoid fever, not only at York but at other similar resorts. The extent of this prevalence is not generally realized and it is desirable that recreation seekers should be intelligently instructed about so-called "vacation typhoid" or what used to be known as autumnal fever. This can be done only by freely publishing the truth concerning typhoid as of all other contagious diseases, a policy which, whenever pursued, has always been shown to be followed by good results.

The town of York is one of not a few summer resorts which has met its local problems of public health in a model manner; but there remain many others which could wisely and profitably take example by its lesson. The two essentials of the method by which this excellent result was accomplished were, first, the replacement of the old-fashioned, inadequate and clumsy board of health by a full time health officer; second, the voting of an adequate appropriation thoroughly to carry out the needed reform. Although in this instance the annual appropriation amounted to only \$1.00 per capita, that sum, as a matter of fact, is proportionally greater than that which any other American city spends directly for public health. Similar methods and a proportionate appropriation in every American city and town might well be ex-

pected to accomplish equally creditable results. No community, whether that of a health resort or of an agricultural or industrial center, can longer afford to depend upon nature and luck for a clean bill of health, but must rely rather on the intelligence and efficiency of its local public health officers.

MEDICAL NOTES

ENDOWMENT FUND FOR MEDICAL RESEARCH.—Report from Minneapolis on February 9, states that the Drs. Mayo of Rochester, Minn., have decided to establish a \$1,000,000 foundation for medical research, to be placed under certain restrictions in the hands of a board of regents in the University of Minnesota. It is planned that the interest of this fund shall be used annually for research by graduate medical students of the University. At a meeting of the faculty of the University of Minnesota Medical School on February 8, this project was approved and has been referred to the advisory board.

UNITED STATES DEATH RATE IN 1913.—A report issued by the United States Census Bureau on February 8, shows that in 1913 the death rate of the United States was 14.1 per thousand of the estimated population in the registration area, as compared with 13.9 per thousand in 1912. The total number of deaths in the registration area, which contains about two-thirds of the national population was 890,948.

"Washington State showed the lowest rate, being 8.5 per 1000, while New Hampshire's was the highest with 17.1 per 1000. The rate in Massachusetts was 15. The lowest rate shown in 1913 by any of the fifty registration cities with populations of 100,000 or over in 1910, was that of Seattle, which was 8.4, while Memphis showed the highest with 20.8. Boston's rate was 16.4; Cambridge, 13.5; Fall River 17.2; Lowell, 15.9; Worcester, 15.8. The average age at death for both sexes, from all causes combined was 39.8; for males alone 39.2, for females, 40.6. Nearly 18 per cent. of all deaths were of infants under one year of age, and more than 25 per cent. were of children under five years.

"The death rate from tuberculosis declined from 149.5 per 100,000 population in 1912, to 147.6 in 1913. The rate from cancer rose from 63 per 100,000 in 1900 to 78.9 in 1913. The number of suicides was 9998, the rate being 15.8 per 100,000, compared with 16 in 1912."

TUBERCULOSIS AMONG WORKINGMEN.—A new campaign for closer co-operation with labor unions and other groups of workingmen is announced by The National Association for the Study and Prevention of Tuberculosis.

A committee has been appointed with Dr. Theodore B. Sachs, President of the Chicago Tuberculosis Institute, as chairman, to formulate plans for immediate and future action. Other members of the committee are: Dr. William Charles White, Medical Director of the Tuberculosis League of Pittsburgh, and Dr. David R. Lyman, Superintendent of the Gaylord Farm Sanatorium, Wallingford, Conn.

As the first step in the campaign, a special health bulletin has been prepared for the labor papers, and will be sent out monthly in coöperation with members of the International Labor Press Association. A second step in the plan is an investigation into the various special experiments of co-operation between workmen and the anti-tuberculosis movement that have been carried on in this country. Such work as that of the tuberculosis relief associations in Hartford, New Haven, Meriden, and other Connecticut cities; the Trades Union Sections of the Buffalo and Newark Anti-Tuberculosis Associations; the work of the Factory Committee of the Chicago Tuberculosis Institute; the Tuberculosis Pavilion of the Albany Federation of Labor; the "Overlook Plan" of Massachusetts; and other similar efforts are being studied and reported upon. These reports will be made the basis for recommendations and further study in industrial communities throughout the country.

NEW YORK CITY'S DEATH RATE CONTINUES LOW.—The mortality noted during the past week was remarkable for the low rate recorded. There were 1,460 deaths reported as against 1,628 deaths during the corresponding week in 1914, a decrease in the absolute figures of 168 deaths, and if the increase in population be taken into consideration, a relative decrease of 236 deaths.

Every prominent cause of death showed a decreased mortality, especially measles, diphtheria and croup, scarlet fever, whooping cough, typhoid fever, diarrheal diseases under five years of age, organic heart diseases, acute diseases of the respiratory organs, influenza, tuberculosis of all organs, Bright's disease and nephritis, and violence.

The greatest decrease in mortality was shown in the number of deaths reported from organic heart diseases, the pneumonias, and the deaths from accident. At all age groups, with the exception of infants under one year of age, the mortality was lower than in the corresponding week of 1914.

The death rate for the first five weeks of this year was 14.08 per 1000 of the population as against a rate for the corresponding period of 14.75, a decrease of .67 of a point.

EUGENICS AND MARRIAGE IN WISCONSIN.—Report from Madison, Wis., on February 6, states that during the year 1914, the first year of the operation of the new eugenics marriage law, only 13,300 marriages were recorded in that state as against 17,332 during 1913. If the quality of

these marriages is demonstrated to have been improved, the eugenic law may be considered to have fulfilled its object.

CASE OF LEPROSY IN CHICAGO.—Report from Chicago states that a case of leprosy was discovered in that city on February 5 in the person of a recent Italian immigrant working as a night watchman. The patient has been deported.

EPIZOÖTIC OF FOOT AND MOUTH DISEASE.—On February 5 a dozen new cases of foot and mouth disease were discovered in the local stockyards at Cincinnati, Ohio, which were thereupon quarantined. These cattle had been shipped from Indianapolis. As a result of this discovery and of other recrudescence of infection in Chicago, Louisville, Buffalo, Pittsburgh and Jersey City, a new quarantine order was issued on February 6 by the department of agriculture modifying the quarantine regulations in these regions. On the same day the Bureau of Animal Industry announced that the total loss from the present epizootic amounts to \$3,399,110.

Twenty states and the District of Columbia have been more or less affected since last October. By January 31 the work of checking the disease was practically completed in all but seven states and further progress is continually being made. There have been slaughtered 46,268 cattle, 47,735 swine, 7,151 sheep and 22 goats.

The cost of the epizootic in other states has been: Illinois, \$1,338,854.18; Pennsylvania, \$750,000; New York, \$293,224; Rhode Island, \$47,084.50; Connecticut, \$35,787.10.

In Massachusetts the cost thus far has been \$72,425, and an appropriation of \$100,000 has been asked of the General Court to meet this and further liabilities. Statistics show that in Massachusetts the disease has appeared in 32 towns and 794 herds. The total appraisal of animals was \$119,050 and of property destroyed \$25,000, of both of which the State pays one-half and the federal government one-half. Several new cases of the disease were discovered on February 8 at Waltham, Mass., and on February 9 at Arlington, Mass. In both places quarantine has been reestablished.

EUROPEAN WAR NOTES.—Report from Vienna on February 4 by way of Amsterdam and London states that small-pox is at present epidemic in the Austrian capital but the number of cases is not stated.

In an address before the Surgical Society of Paris on February 6, Dr. Truffier is reported to have said that of the 14,000 surgeons in the French Army, 6,500 are now at the front. Up to the close of December 93 surgeons had been killed, 260 wounded, 440 were missing and 155 had been mentioned in orders for gallantry on the field of battle.

The Constantinople Chapter of the American Red Cross, after a recent conference with Dr.

Suleman Nouman, inspector general of the Turkish Military Sanitary Service, has sent to the Ottoman war department a list of American Missionary Hospitals in Asia Minor, having a total of approximately 1000 available beds. It is intended that these hospitals shall be used in meeting war emergencies in caring for the wounded of all nations.

Of the 15 institutions listed, two are the French and British hospitals in Constantinople, now under the American Red Cross. On the others, 10 are hospitals connected with mission stations of the American Board while one conducted under an independent board of trustees is officered by men formerly connected with the American Board.

The Turkish Ministry of War has been asked to furnish certain supplies—drugs, absorbent cotton, oil, coal, etc.—for the British and French hospitals in Constantinople, but nothing is said about the furnishings for the hospitals in the interior.

Prior to the outbreak of the war the total number of physicians in Europe was approximately 200,000, of whom there were 48,000 in Great Britain, 32,000 in France, 26,000 in Germany, 24,000 in Italy, 20,000 in Russia, 13,000 in Austria, 12,000 in Belgium and 8,000 in Spain. The proportion of physicians to population is much greater in Great Britain than in any other country, but it is highest of all cities in Brussels, where there is one to every 400 inhabitants.

Three more American surgeons have recently left this country for field service in Europe. Dr. Earl B. Downer of Lansing, Mich., will go to the first American Red Cross hospital unit at Belgrade; Dr. James E. Stowers of Kansas City, and Dr. E. L. Gilchrist of Gainsville, Texas, to the American Red Cross hospital at Paignton, England.

Report from Vienna by way of Washington, D. C., on February 8 states that the Red Cross badge of honor of the second class has been conferred upon Drs. MacDonald, Jewett and Miller of the American Red Cross hospital at Budapest. Report from Vienna by way of London on February 9 states that Surgeon General Philip Peck, chief of the Austrian Army Medical Corps, has died of typhus fever contracted during an inspection trip to the camps of the Russian prisoners in Austria.

A recent correspondent of the *British Medical Journal* who has been in charge of an ambulance in France, has investigated some of the psychological consequences of experience on the battlefield and in the trenches. "Neurotic subjects, as one would expect," he says, "react in a most striking fashion to the shock of explosions in their immediate vicinity. Some develop a tendency to somnambulism and are met wandering about the premises with terror and anxiety depicted on their faces in anxious search of their regiments. Short of somnambulism the dread of losing contact with their fellows seems to be felt with extreme frequency, and horror of isolation con-

stitutes the commonest nightmare of men in the first fighting line. They dream that they are wandering through endless trenches as complicated as an artificial maze, or are picking their way through lonesome forests whence all but they have fled. The slightest noise during sleep calls up visions of exploding shells or the tramp of armed men, throwing them into a frenzy of shouting terror, to the indignation of their resting fellows. Oddly enough, these men are as brave as the rest in face of real danger. Another common night terror is the dream of a sudden call to arms and the inability to find some indispensable article of attire or combat, a conception productive of intense mental agony. Live shells naturally occupy a large share of subconscious attention, and an exasperating nightmare is the discovery in one's bed of a shell ready and willing to burst, associated with the usual nightmare incapacity to execute the necessary movements to get rid of it. Several men have had dreams centering round the inability to withdraw the bayonet from the enemy's body when urgently required for self-defence. Numerous instances of "traumatic hysteria" are met with in which men suddenly roused from deep sleep by explosions, develop the characteristic paralyses and disturbances of sensation. In one case there was marked limitation of the field of vision and inability to connect letters into words; the man could read the letters, but could not pronounce the word when spelled nor write the word when pronounced. Insomnia and more or less troublesome restlessness are also common consequences of the strain on the nervous system of actual warfare."

On February 12 the total of the New York Belgian Relief Fund amounted to \$918,016.98; the New York Red Cross Fund to \$457,583.86; the American Jewish Relief Fund to \$458,792.05; the American Ambulance Hospital Fund to \$325,929.86; and the Committee of Mercy Fund to \$117,904.42.

On February 13 the total of the New England Belgian Relief Fund amounted to \$197,573.77; Massachusetts Red Cross Fund to \$109,723.12; and the American Polish Relief Fund to \$20,582.77.

BOSTON AND NEW ENGLAND.

DEDICATION OF THE CHAPIN MEMORIAL BUILDING.—On Thursday of last week, February 11, the new Frederick Wilcox Chapin Memorial Building of the Springfield (Mass.) Hospital was formally dedicated with appropriate exercises. A eulogy of Dr. Chapin was pronounced by Dr. Charles P. Hooker. The building was presented by Mr. George D. Pratt and accepted in behalf of the trustees by Col. Stanhope E.

Blunt. The building is given in memory of the late Dr. Chapin of Springfield by some of his many friends.

SOCIAL SERVICE AT THE MASSACHUSETTS GENERAL HOSPITAL.—On Tuesday of last week, February 9, the annual meeting of the Social Service Department of the Massachusetts General Hospital was held in the out-patient department under the chairmanship of Dr. Richard C. Cabot. Dr. Frederick A. Washburn spoke on "Advantages and Limitations of Social Service from the Point of View of an Administrator"; Dr. Hugh Cabot on "Hospital Social Service as a Laboratory of Democracy," and Dr. W. S. Wright on "Social Work as Seen by an Interne."

INFANT MORTALITY IN BOSTON.—At a recent meeting of the Board of Trustees of the Boston Milk and Baby Hygiene Association, it was reported that the total number of babies under the supervision of the Association in January, 1915, was 1815, an increase of nearly 500 over the corresponding month last year. The Association voted to support a bill (Senate No. 78) "To Protect the Public Health Against Danger from the Sale of Impure Milk and Cream."

During the past four years Boston has risen from seven to second rank among the ten largest cities in the United States with an infant mortality rate below 160. The present standing of these cities in regard to infant death rate per thousand births during the first year of life is as follows:

New York	94.6
Boston	103.4
St. Louis	103.4
Pittsburgh	115.2
Cleveland	116.4
Philadelphia	117.6
Buffalo	121.5
Detroit	122.4
Chicago	132.7
Baltimore	154.6

Mr. George R. Bedinger, director of the Boston Milk and Baby Hygiene Association, has recently made the following statement of the increase in work of the Association during this period:

"As the main agency doing directly preventive and educational work for babies, the Milk and Baby Hygiene Association during 1910 cared for 1870 babies in nine milk stations. In four years the increase has been over 100% in babies supervised and 33% in baby health stations.

"During 1914 in 12 milk stations the Association supervised the health of 4097 babies. Nurses' visits to the homes of the little babies rose from 38,805 in 1910 to 50,221. In 1910 there were 10,847 visits by mothers and babies to the

'well baby clinics' held weekly at the milk stations.

"In 1914 these visits to consult the physicians about the babies' feeding and care were 19,673."

In this connection it is of interest to note the recently published annual report by Miss Julia C. Lathrop, chief of the Federal Children's Bureau to the department of labor, on the investigation into infant mortality made by the Bureau at Johnstown, Pa. In the poorest sections of this city the infant mortality was 271 per thousand, more than five times that of the better residential districts.

"Babies whose fathers earned \$10 a week or less, died at the rate of 256 per thousand, while those whose fathers earned \$25 or more a week, died at the rate of 84 per thousand. Artificially fed babies died at a much more rapid rate than breast fed babies. Only 46.6 babies per thousand died under one year of age, when breast fed at least three months, as against 165.8 per thousand who died when fed with artificial foods. When mothers were employed a large part of the time in heavy work, babies died at a rapid rate. In one group of nineteen mothers whose babies all died, fifteen had been keeping lodgers. In houses where water had to be obtained from outside, the death rate was found to be 198 per thousand, as against 118 per thousand in houses where water was supplied by pipes."

Similar investigations are now being made by the Bureau at Lancaster, N. H., and Saginaw, Mich. In the preface to her report Miss Lathrop writes as follows of the general social importance of the subject of infant mortality:

"Infant mortality is a subject of profound social importance. The modern view has ceased to be fatalistic; infant mortality is now regarded as a preventable waste, injurious to survivors as well as destructive to infants, and cruelly increasing the burden of rearing a family. Sir Arthur Newsholme, the great English authority, has said, 'Infant mortality is the most sensitive index we possess of social welfare and of sanitary administration, especially under urban conditions.' Naturally, the United States has as yet no means of measuring the extent and significance of its infant mortality. If it were practicable, it would be illuminating to visit each one of the 2,500,000 children who, it is estimated, are born in this country yearly, and to take note of the varying social and economic conditions under which some 300,000 of them die and the others survive. As this is manifestly impossible, the nearest approach is to consider certain communities typical of the whole, and it is believed that in the course of a few years' study such data can be presented as will give the United States a fairly adequate measure of the conditions under which American-born infants survive or perish, and of the possibilities of modifying those conditions by local action."

The lowest infant mortality rate in the world is that of New Zealand which, in 1910, was only 51 and in 1913 only 38 per thousand births.

Massachusetts Medical Society.

STATED MEETING OF THE COUNCIL.

A STATED meeting of the Council was held at the Boston Medical Library, February 3, 1915, at 12 o'clock, noon, the president being in the chair and the following seventy-one councilors present:

BARNSTABLE.
E. E. Hawes.

BERKSHIRE.
L. A. Jones.

BRISTOL NORTH.
A. R. Crandell.
R. D. Dean.

BRISTOL SOUTH.
E. F. Cody.
J. H. Gifford.
H. G. Wilbur.

ESSEX NORTH.
R. V. Baketel.
F. W. Snow.

ESSEX SOUTH.
N. P. Breed.
W. G. Phippen.
H. E. Sears.

FRANKLIN.
G. P. Twitchell.

HAMPDEN.
T. L. Bacon.
J. M. Birnie.
G. D. Henderson.
M. B. Hodskins.

MIDDLESEX SOUTH.
F. E. Bateman.
J. E. Cleaves.
C. H. Cook.
H. F. Curtis.
G. W. Gay.
A. A. Jackson.
C. E. Prior.
E. H. Stevens.
J. O. Tilton.

NORFOLK.
G. G. Bulfinch.
P. W. Carr.
H. C. Ernst, *chairman*.
G. W. Kaan.
E. W. Finn.

G. H. Francis.
T. F. Greene.
T. J. Murphy.
W. H. Robinson.
B. E. Sibley.
C. F. Stack.

NORFOLK SOUTH.
O. H. Howe.
A. E. Paine.
F. G. Wheatley.

SUFFOLK.
J. W. Bartol.
H. I. Bowditch.
E. M. Buckingham, *treas.*
W. L. Burrage, *sec'y*.
David Cheever.
E. A. Codman.
J. A. Cogan.

R. W. Lovett.
J. L. Morse.
A. G. Richardson.
M. A. Smith.
R. M. Smith.
G. B. Shattuck, *chairman*.
Beth Vincent, *chairman*.
H. F. Vickery.
C. F. Withington.

WORCESTER.
W. P. Bowers.
C. A. Church.
W. J. Delahanty.
Homer Gage.
David Harrower.
G. O. Ward.
L. F. Woodward.
S. B. Woodward.

WORCESTER NORTH.
H. W. Page.

The minutes of the last meeting were read and accepted.

The president read an obituary of Councilor Harry Clifton Boutelle, who died January 24, 1915 (see BOSTON MEDICAL AND SURGICAL JOURNAL, February 4, 1915, page 200.)

The reports of the committee appointed to consider the petitions of the following named Fellows for reinstatement in the Society were adopted, voting their restoration to the privi-

leges of Fellowship provided they discharge all indebtedness within one month: A. W. Parsons, W. H. Coon, J. W. O'Connor, J. F. Moore. Petitions for reinstatement from the following were referred to committees: J. A. Ceconi, F. X. Mahoney, R. F. Burns, C. H. Phillips, E. O. Tabor, J. J. Sullivan.

The president nominated and the council elected the following delegates:

To National Legislative Committee and Council on Health and Public Instruction of the American Medical Association at Chicago, M. J. Rosenau. To Conference on Medical Education and Meeting of Association of American Medical Colleges at Chicago, H. C. Ernst.

Members of House of Delegates, American Medical Association, for two years:

Hugh Cabot, Boston, Alternate, F. B. Lund, Boston. B. W. Paddock, Pittsfield, Alternate, E. F. Cody, New Bedford.

To Rhode Island Medical Society:
A. S. MacKnight, Fall River, W. H. Butler, Fall River.

To Connecticut State Medical Society:
A. L. Cooley, Chicopee Falls, G. Z. Goodell, Salem.

To Main Medical Association:
C. H. Bangs, Lynn; F. W. Snow, Newburyport.

To New Hampshire Medical Society:
G. H. Gray, Lynn; W. H. Merrill, Lawrence.

Dr. R. I. Lee was appointed to fill a vacancy in the Standing Committee on Public Health.

The treasurer's report was read by Dr. Buckingham and the report of the Auditing Committee by Dr. Blakely (see page 277).

Voted, To accept the reports.

The following report of the Committee on Membership and Finance concerning membership, was read by Dr. Green:

The Committee on Membership and Finance makes the following recommendations:

1. That the following named Fellows be allowed to retire, under the provisions of Chapter I, Section 5, of the by-laws:

Abbott, Stephen Wendell, of Lawrence.
Booth, Edward Chauncey, of Somerville.
Chipman, William Reginald, of Chelsea.
Driver, Stephen William, of Cambridge.
Gibbs, Locero Jackson, of Chicopee Falls.
Pillsbury, Warren Wilbur, of Newburyport.
Prescott, Charles Dudley, of New Bedford.
Robinson, Lucy Morton, of Brockton.
Sanborn, Edwin Aaron, of Somerville.
Stutson, William Peckham, of Cummington.
Tucker, Edward Tobey, of New Bedford.
White, Emory Lincoln, of Somerville.
Woods, George Lyman, of Springfield.

2. That the following named Fellows be allowed to resign, under the provisions of Chapter I, Section 7, of the by-laws:

Arms, Burdette Loomis, now of the University of Texas.

Bruce, Harold Milton, of Plymouth.

Dean, Charles Henry, now of Salisbury, Vt., formerly of Northampton.

Eaton, William Edward, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Gaffney, Mary Evangeline, now at The Convent, Newport, R. I.

Karsner, Howard Thomas, now of Western Reserve School of Medicine, Cleveland, Ohio.

Parker, Edwin Monroe, now of Reed's Ferry, New Hampshire.

Robinson, Samuel, now at the Mayos' Clinic, Rochester, Minnesota.

Smith, Earl Moulton, of 248 E. Main St., Amsterdam, N. Y.

Wright, George Hermann, of New Milford, Conn.

3. That the following named Fellow be allowed to resign, as requested by the Committee on Ethics and Discipline:

Papoulacos, Panagiotis, of 176 Huntington Avenue, Boston.

4. That the following named Fellow be deprived of the privileges of Fellowship for non-payment of dues, under the provisions of Chapter I, Section 8, of the by-laws:

Brown, Joseph, formerly of Worcester, now of Des Moines, Iowa.

For the Committee on Membership and Finance,
CHARLES M. GREEN, *Chairman*.

Voted, To accept the report and adopt its recommendations.

Dr. Beth Vincent reported for the Committee of Arrangements and sketched the plans of his committee for the annual meeting. Two alternatives were outlined, one to have the meeting at the Copley-Plaza Hotel as last year, and the other to have most of the meetings in the Boston Medical Library and the dinner elsewhere. The committee favored the former plan at an estimated expense to the Society of \$1,775, an itemized estimate being furnished. Dr. G. W. Gay spoke on a proposition which had been advanced at a previous meeting of the Council, namely, that those who attend an annual dinner of the society should defray all of the expense of the dinner. He favored such a plan in the interests of economy and to promote the affiliation between the BOSTON MEDICAL AND SURGICAL JOURNAL and the Society and made a motion to this effect. After considerable discussion the motion was put to a vote and lost.

Dr. G. B. Shattuck reported for the Committee on Publications and Scientific Papers that Dr. Theodore C. Janeway will be the Shattuck Lecturer in the year 1916.

The following report of the Committee on Membership and Finance, concerning finance, was read by Dr. Green:

The Committee on Membership and Finance makes the following recommendations:

1. That a dividend of \$4000, from the balance remaining in the treasury on December 31, 1914, be apportioned among and paid to the district societies, in accordance with the provisions of Chapter VII, Section 3, of the by-laws.

2. That appropriations for Standing Committees for the financial year 1915 be made as follows:

For the Committee of Arrangements.....	\$1775
For the Committee on Medical Education and Medical Diplomas.....	50
For the Committee on State and National Legislation	250
For the Committee on Public Health.....	75

3. That to make possible the continuance of the

affiliation of this Society with the BOSTON MEDICAL AND SURGICAL JOURNAL, the Council appropriate for the year 1915 the sum of \$9500, this sum to be reduced by such sum as may be raised by special subscription.

4. That the Advisory Committee representing the Massachusetts Medical Society on the Board of Management of the BOSTON MEDICAL AND SURGICAL JOURNAL be authorized by the Council to secure pledges towards the maintenance of the JOURNAL.

For the Committee on Membership and Finance,

CHARLES M. GREEN, *Chairman*.

After several questions by councilors had been answered by Dr. Green and the president it was,

Voted, To accept the report and adopt its several recommendations.

Dr. E. E. Hawes spoke on the desirability, from the standpoint of Fellows who live at a distance, of having the annual dinner in the middle of the day, because of the amount of time required to attend a dinner in the evening. No action taken.

Dr. Gay referred to a suggestion made in an editorial in the BOSTON MEDICAL AND SURGICAL JOURNAL of October 1, 1914, entitled "The Minister and the Doctor," to the effect that there might be coöperation between the Massachusetts Federation of Churches and the Massachusetts Medical Society to perfect a plan of joint action to better health conditions in the State. He read this extract from a letter written to the secretary by the Rev. Samuel C. Bushnell, chairman of the Committee on Philanthropies of the Federation, dated January 27, 1915:

"At a meeting of the Committee on Philanthropies of the Massachusetts Federation of Churches it was voted, this afternoon, to overture the Council of the Massachusetts Medical Society to see if some method of coöperation might not be devised whereby the doctors and ministers throughout the state might get together for the benefit of their local communities.

"The plan met with the heartiest approval of all present—six of our committee of seven, Hon. Mr. Luce of Somerville being absent. If your Council would appoint a committee to meet as many of our committee as could get together on the day chosen we could discuss the general question and possibly reach some decision which might appeal to both organizations."

The president said that the Federation of Churches was composed of representatives of practically all the religious denominations and he understood that the Committee on Philanthropies was ready to favor desirable legislation, as well as to work with a Committee from our Society. On motion by Dr. Gay it was,

Voted, That the Committee on Public Health of the Massachusetts Medical Society be hereby authorized to coöperate with the Committee on Philanthropies of the Massachusetts Federation of Churches in such activities, having for their object the improvement of sanitary and social conditions of this Commonwealth, as the said committee may think wise and proper.

DR. E. H. BRIGHAM presented the following memorandum concerning an early meeting place and the fourth president of the Society:

In 1783 the land now substantially covered by the Phillips Building on the north corner of Tremont Street and Hamilton Place was occupied by what was called the "Manufactory House," which belonged to the Commonwealth of Massachusetts and had been used as a barracks during the Revolution. On March 20, 1783, the General Court passed a resolve permitting the Academy of Arts and Sciences and the Massachusetts Medical Society to make use of and improve the room in the Manufactory House, which had for some time past been occupied for a school by Mr. Vinal.

On February 13, 1784, the General Court passed a resolve that Samuel Phillips, Jr., Caleb Davis and John Rowe be a committee to make sale of the Manufactory House with the land thereto belonging. In pursuance of this resolve the estate was sold and by deed dated March 24, 1784, conveyed by this committee to the Massachusetts Bank. (Registry of Deeds, Suffolk County.)

"At a meeting of the American Academy of Arts and Sciences at the University in Cambridge, November 13, 1782,

Voted: That the Hon. Cotton Tufts, Esq., Ebenezer Storer, Esq., and the Rev. Mr. Howard be a committee to join with a committee, in case one should be appointed for the purpose by the Medical Society at their next meeting, in procuring a convenient room in the Town of Boston, in which both societies may hold their respective meetings."

"At a meeting of the American Academy of Arts and Sciences, in the County Courthouse and by adjournment in the Manufactory House in Boston, May 27, 1783,—

Whereas, The General Court did by a Resolve dated (no date given) grant to the American Academy and the Medical Society the use of a room in the Manufactory House in Boston in which to hold their respective meetings during the pleasure of the Court; and whereas certain repairs are necessary in said room,

Voted: That the Hon. Cotton Tufts, Esq., Ebenezer Storer, Esq., and the Rev. Simeon Howard be a committee to join a committee of the Medical Society in making such repairs as they may judge necessary at the expense of the two societies equally; and in framing such regulations respecting the room as they may think proper and report at the next meeting."

"A Petition of Mons. John Mary requesting liberty to teach the French language in the room granted to this Academy and the Medical Society by the General Court was read, whereupon

Voted: That Ebenzer Storer, Esq., the Rev. Dr. Cooper and the Hon. Robert T. Paine, Esq., be a committee to join a committee of the Medical Society (in case one should be appointed) in considering and determining on said Petition, their doings to be valid 'til the further order of

the Academy." (Records American Academy Arts and Sciences.)

Three meetings of the Academy were held in the "Manufactory House," December 31, 1783, January 20, and April 1, 1784.

The Hon. Cotton Tufts, Esq., mentioned is Dr. Cotton Tufts of Weymouth, a state senator, who was an original incorporator and second vice-president of the Massachusetts Medical Society, 1785-1787; and fourth president, 1787-1795; also an incorporator of the American Academy of Arts and Sciences.

His portrait, given to the Library by William Tufts Brigham, A.B., Harvard, 1862, of Honolulu Hawaii, is now in the Fifield Room of the Boston Medical Library and was shown to the Council by the librarian.

Dr. Gay addressed the Council on the need of better care for the inebriates of the State. He said that it had been suggested that non-criminal inebriates be given an indeterminate sentence to the Norfolk State Hospital, working through the out-patient department in Boston, rather than follow the present custom of committing them to the House of Correction at Long Island, as is the case in the County of Suffolk. The latter plan, while not being humane, was a very large expense to the county. He thought that the Society should work to forward this movement. The chairman said that the Committee on State and National Legislation was prepared to promote this proposition.

Adjourned at 1.20 p. m.

WALTER L. BURRAGE, *Secretary.*

MASSACHUSETTS MEDICAL SOCIETY.

TREASURER'S REPORT FOR THE YEAR 1914.

Mr. President and Fellows of the Society:

Your treasurer has to report the finances of the Society for the year 1914 as follows:

RECEIPTS.

Balance January 1, 1914 \$11,990.74
Assessments paid to District Treasurer:

Barnstable	\$ 173.00
Berkshire	353.00
Bristol North	287.00
Bristol South	616.00
Essex North	774.00
Essex South	991.00
Franklin	173.00
Hampden	979.00
Hampshire	311.00
Middlesex East	370.00
Middlesex North	572.00
Middlesex South	2,334.00
Norfolk	2,047.00
Norfolk South	255.00
Plymouth	494.00
Suffolk	3,156.00
Worcester	1,235.00
Worcester North	343.00

\$ 15,463.00

Assessments to Treasurer	1,101.00
Assessments at annual meeting..	285.00
Sale of dinner tickets	715.00
Interest on Massachusetts bonds	560.00
Interest on funds subject to New England Trust Co.	\$181.19
check:	
Old Colony Trust Co.	127.17
	<hr/>
	308.36
Interest on annuity policies of the Mass. Hospital Life Ins. Co.	867.86
Interest on Savings Bank de- posits	164.58
Sale of copy of Directory	1.00
	<hr/>
	\$31,456.54

EXPENSES.

President's expense:	
Printing and postage	\$ 12.65
Traveling	11.63
	<hr/>
	\$24.33
Secretary's expense:	
Record book	\$ 1.25
Printing and stamped envelopes	333.65
Stenographers at Section meet- ings	70.00
Engrossing	20.30
Addressing programs	15.00
Directories	12.00
Incidentals	29.29
	<hr/>
	\$481.49
Librarian's Expense:	
Index cards	\$ 14.00
Files	3.50
Postage and expressage	142.05
Printing and postal cards	56.50
Typewriting	10.00
	<hr/>
	\$226.05
Treasurer's expense:	
Printing and stamped envelopes	\$152.17
Stationery and account books.	15.15
Clerical work	60.74
Treasurer's bond	37.50
Rent of box, Old Colony Trust Co.	10.00
Incidentals	4.33
	<hr/>
	\$279.89
Bank charges	1.00
District Treasurers' expense:	
Commissions	\$773.15
Postage, printing, etc.	229.51
	<hr/>
	\$1,002.66
Supervisors' expense	24.88
Censors' expense	540.45
Shattuck lecture	200.00
Cotting lunch	286.05
*BOSTON MEDICAL AND SURGICAL JOURNAL	3,175.75
Delegates to American Medical Association and its committees	286.67
Rent	750.00
Salaries	1,700.00
Return of overpaid assessments less commission	26.60
Annual dividend	3,000.00
Committee on publications and Scientific Papers:	
Printing and Distributing....	869.55

Committee on Ethics and Disci- pline:	
Mileage	\$ 12.00
Committee on State and National Legislation:	
Legislative Bulletin	\$ 10.00
Stenographer	22.78
Printing envelopes and station- ery	25.50
Incidentals	48.00
	<hr/>
	\$106.28

Committee of Arrangements:	
Bond boxes	\$ 1.80
Printing and stamped envelopes	107.00
Stationery58
School supplies	2.55
Badges	4.90
Stereopticon	5.00
Clerks	60.00
Police	32.00
Music	125.00
The Copley-Plaza Hotel.....	3,053.75
Cigars	77.61
	<hr/>
	\$3,470.19

Committee of Chairman of the Committee of Arrangements and Chairmen of Sections:	
Mileage	7.22
Committee of Nine:	
Stenographer	\$ 28.18
Mileage	50.54
	<hr/>
	78.72
	<hr/>
	\$16,549.78

Balance January 1, 1915	\$14,906.76
Balance January 1, 1914	11,990.74
	<hr/>
Increase over last year.	\$ 2,916.02

Against this increase must be set an indeterminate sum representing the amount still to be paid to the BOSTON MEDICAL AND SURGICAL JOURNAL.

The balance is distributed as follows:

Deposit in the New England Trust Co....	\$7,242.63
Deposit in the Old Colony Trust Co.....	7,697.13
	<hr/>
	\$14,939.76
Deduct checks still out.....	33.00

Balance called for..... \$14,906.76
The change in the deposit from the Bay State Trust Co. to the Old Colony Trust Co. is because of the consolidation of these two institutions.

PERMANENT INVESTMENTS.

Shattuck Fund:	
Annuity policy, Massachusetts Hospital Life Insurance Co.....	\$ 9,166.87
Phillips Fund:	
Massachusetts 3½ per cent. bond.....	10,000.00
Cotting Fund:	
Deposit in Roxbury Institution for Sav- ings	1,000.00
Deposit in Provident Institution for Sav- ings	1,000.00
Deposit in Suffolk Savings Bank.....	1,000.00
Permanent Fund:	
Annuity policy in Massachusetts Hospital Life Insurance Co.....	11,253.30
Massachusetts 3½ per cent. bonds.....	6,000.00
Deposit in Franklin Savings Bank.....	1,074.48
	<hr/>
	\$40,494.65

There has been no change in these funds during the year.

EDWARD M. BUCKINGHAM, *Treasurer.*

* It appears by bills presented by the JOURNAL in July and October, that up to that time \$3,399 had been collected upon the guarantee subscriptions.

REPORT OF AUDITING COMMITTEE.

The undersigned, a duly appointed committee, having examined the books of the Treasurer, find them correctly cast and properly vouched, and also that he has in his possession the securities called for.

DAVID N. BLAKELY.

JAMES LINCOLN HUNTINGTON.

Boston, Feb. 1, 1915.

Obituary.

THOMAS BRYANT, F.R.C.S., M.Ch., M.D.

MR. THOMAS BRYANT, who died in London, on Dec. 30, 1914, was born in Kennington on May 26, 1828, the son of a surgeon. He was educated at King's College, and in 1846 entered the Guy's Hospital Medical School. He qualified as M.R.C.S. in 1849 and as F.R.C.S. in 1853. In 1857 he was appointed assistant surgeon at Guy's Hospital, and in 1858 lecturer on clinical and in 1859 on operative surgery. In 1871 he became full surgeon at Guy's Hospital and in 1872 first published his famous text-book on the practice of surgery, a second edition of which appeared in 1876 and a third in 1879. This work was a monument in the progress of surgery since, prior to its time, there had been published but one other large system of surgery, that of Erichsen.

In 1875 Mr. Bryant was appointed lecturer on surgery at Guy's Hospital and continued active there in the practice of his profession until his retirement as consulting surgeon in 1888. In that same year he delivered the Hunterian Oration and in 1889 the Bradshaw Lecture. From 1891 to 1894 he was president of the Royal College of Surgeons of England and from 1891 to 1894 served as its representative on the general medical council. In 1896 he was appointed Sergeant Surgeon Extraordinary to Queen Victoria and subsequently became Surgeon in Ordinary to King Edward and King George. He was a member of the Medical Society of London, the Hunterian Society, the Clinical Society and the Royal Medical and Chirurgical Society. He had received honorary medical degrees from the Royal University in Ireland and the University of Dublin.

Mr. Bryant was married in 1862 and is survived by three daughters and four sons.

Mr. C. H. Golding-Bird, writing of Mr. Bryant in the *Lancet*, speaks as follows of the latter's personal characteristics:—

"A handsome man, of commanding presence, with a personality that impressed itself on others, genial, kindly, and always ready to lend an ear to any that sought his advice. Bryant was the friend of all who knew him, whether student, colleague, or patient. The student felt that in him he had a friend to whom he could go for ad-

vice at all times, and never fail to get his sympathy and help. To his dressers' mistakes he was lenient, and whilst he never overlooked anything nor hesitated to correct, he at the same time explained and instructed so as to avoid a repetition of a similar mischance. As a colleague he was valued by all, and though 'once upon a time' there arose a serious difference between himself and a colleague that even threatened the peace of the hospital, he met his quondam friend in the open court of the operating theatre at the instance of their other colleagues, and both men publicly shook hands and thus closed the incident forever. Beyond this nothing ever happened to disturb the harmony with which Bryant performed his public duties at Guy's Hospital; and those who knew him personally will always cherish the memory of him as of a true friend, a courteous gentleman, and if not exactly a pioneer, at any rate a splendid example of the British surgeon."

Miscellany.

THE HEALTH OF YORK.

A BRIEF review of the situation at York, Maine, in regard to public health is not amiss at the opening of the new year. In the late summer and early autumn of the past year there were a number of cases of typhoid fever in York Harbor and the vicinity. While these cases were not enough in number and severity to constitute a serious epidemic, the mere presence of the disease in such a popular sea-side resort naturally gives rise to considerable alarm. York met the situation in the following way, which should serve as a model to any other town in similar circumstances. There was no attempt to conceal the fact of the existence of the disease and its extent, the authorities very properly feeling that the way to meet any danger was to face it in the open.

At a meeting of the Village Improvement Society, a committee was appointed to confer with the selectmen and the board of health. As the result of this conference, a town meeting was held late in September and money was voted to meet the cost of a sanitary survey of the town which was made by Professor Milton J. Rosenau of Harvard University. While nothing very startling was discovered, a situation was found which showed that there were conditions which might, and probably did, affect the public health. As a result of the report of Professor Rosenau, a town meeting was held at which it was voted to employ a health officer, and \$2500 was voted for his salary and the expenses incidental to the work.

The town is to be congratulated upon the

selection of Mr. William Eustis Brown as its health officer. Mr. Brown has had a thorough training in sanitation and preventive medicine both at the Massachusetts Institute of Technology and at Harvard University. He is a graduate of the School for Health Officers and has had a varied and wide experience in sanitary work of all kinds, and is well qualified to carry on the work.

This step which York has taken at once places it in the forefront of progress as far as health is concerned. York has determined to safeguard its citizens and all strangers within its gates and give them the security of health that a well ordered sanitary department can furnish. Although blest with natural advantages of an unusual order and admirable location, a charming scenery both of sea and country, and a delightful climate, York is not going to depend upon nature and luck for a clean bill of health. It has been said that "public health is purchasable," the price is moderate and the action of York shows that she intends to enjoy the best attainable protection from disease. Such protection ranks far above any other advantage which a summer resort can enjoy. Many resorts have acted on the policy that a good climate, charm of location and beauty of scenery are sufficient inducements to attract the summer visitor; but nowadays people are more wary and wisely look for more than this before selecting a vacation playground. The visitor wants a clean bill of health for the resort he has chosen and is entitled to have one. York will now be able to furnish this assurance.

There may be some obscurity as to the duties of a health officer in a small town such as York. Cases of communicable disease may arise in any community. Typhoid fever lurks in almost every country district in the land, always ready to strike if the opportunity offers. Some of the 8000 people from various parts of our broad land who visit York annually may introduce infection. It will be one of the duties of the new health officer to ascertain the existence of infectious diseases and take immediate measures to prevent their spread. Cases of such diseases will be traced to their source and practical preventive measures will be applied without delay.

Furthermore, the health officer will examine the sources of water supplies and analyze them. He will inspect the milk supply, visit and examine dairies, see that cows are healthy, that the milk is gathered in a cleanly and safe manner. This is of great importance as disease is often spread through contaminated milk. A little advice as to dairy management is often of great advantage to the milk producer.

Other foods, such as oysters, clams, meat, lettuce, etc., will be inspected by the health officer in order to be sure that the dealers comply with the pure food laws. The health officer will also inspect markets, kitchens, provision shops and store rooms where food is handled and kept. He looks after nuisances, prevents pollution of the

beaches, conducts a campaign against flies and mosquitoes, supervises the harvesting of ice and performs many other duties which are included in the art of hygienic living. He keeps the vital statistics in accordance with modern methods. With careful records he is able to compare the health of York with other communities and to determine whether the measures he is taking are effective; and to trace the progress of health and disease, of births and marriages, and other vital factors affecting every member of the community.

York must some time in the not distant future look forward to the installation of a sewage system. This work must not be undertaken hastily, and information must be collected which will be of service in providing a proper system. To collect such information and to study the local conditions will be a part of the duties of the health officer.

In connection with the position, a chemical and bacteriological laboratory will be equipped where analyses may be made. This laboratory also will be prepared to make blood tests in order to recognize early cases of typhoid fever, to examine throat cultures in order to diagnose diphtheria, and to generally assist the physicians in the early recognition of other infections and to ascertain the time when such cases may be released from quarantine so that they will not menace the community as bacillus carriers.

We may all feel more secure in the health of our families and particularly of our children now that such a work has been undertaken.

(Signed)

JOSEPH P. BRAGDON,
*Chairman of Board of
Selectmen.*

WILLIE W. CUZNER, M.D.
*Secretary of Board of
Health.*

W. T. COUNCILMAN, M.D.
*Chairman of Committee
of Village Improvement
Society.*

CINCHONA OR CHINCHONA

In the issue of the *Medical Press and Circular* for Jan. 20, a Dublin correspondent calls attention as follows to the spelling and history of the name Cinchona, or Chinchona, applied by Linnaeus to Peruvian bark.

"The new edition of the *British Pharmacopoeia* has, I fear, perpetuated the Linnaean spelling Cinchona. Linnaeus sought to honour the memory of the Countess de la Chinchon when in 1742, he named the natural order from which the chinchona bark is obtained Chinconaceae. As the bark was usually put on the market in the condition of powder, it came to be known as the

Countess's powder,' 'Jesuit's powder,' and the 'English remedy,' or 'Talbot's Wonderful Secret for Curing Agues.' On the proposal to alter the spelling by the insertion of the letter h after the initial letter, Murray writes: 'The accepted form is too deeply rooted in botanical and chemical nomenclature to make this expedient.' Withal we should try to perpetuate the name of the illustrious Chinchon family with the introduction of this one of our most precious drugs. The title illustrious is justly borne by the family of the beautiful Lady Ana de Osorio, whose ancestor Ramiro, King of Galicia in 843, is said, by Spanish chroniclers, to have had Saint James as a companion-in-arms at his great victory over the Moors at Clarijo, in which the apostle gave the battle cry of 'Santiago' to Spain. The Lady Ana was born in 1599, and at 16 years old was married to Don Luis de Velasco, who in 1617 became Marquis of Salinas. Two years later the Lady Ana, still young and very beautiful, became both a widow and an orphan. In the autumn of 1621 she married Don Luis Geronimo Fernandez de Cabrera y Robadilla, fourth Count of Chinchon, a descendant of a very ancient family of Catalonia. Soon after their marriage they entertained at Sagovia, their country seat, Charles Prince of Wales and his companion, the Duke of Buckingham. And there are good grounds for believing that it was there that the Prince saw the deaf mutes who had been taught by Pedro Ponce to speak. Sir K. Digby tells us that one of the mutes, Don Pedro Velasco, 'spoke and wrote Latin as well as his mother tongue.'

"In 1628 the Count of Chinchon was appointed Viceroy of Peru, and in 1629 made his public entry into Lima. During his viceroyalty he had the sources of the Amazon explored, he suppressed the revolt of the natives and reformed the conditions under which they lived.

"In 1636 an Indian of Malacotes made Don Francisco Lopez de Cañizares, Corregidor of Lima, acquainted with the properties of quinquina bark, and two years afterwards, when the Countess of Chinchon was suffering from tertian fever, the Corregidor sent her a supply of the native remedy. The medicine was administered by the Court physician, Don Juan de Vegt, and the Countess recovered. On the return of the Count and Countess to Spain in 1640 they were accompanied by their physician, Don Juan de Vega, who brought with him a supply of the valuable bark, which he disposed of under the name of the 'Countess's powder.' "

[NOTE: The error was Linné's: etymologically the name should be Chinchona.—ED.]

Correspondence

REGISTRATION OF NURSES IN MASSACHUSETTS.

BOSTON, MASS., February 5, 1915.

Mr. Editor: Your contention in your editorial criticism of the Bill to amend the requirements for nursing in Massachusetts, seems to be first, an endorsement of the report of the Committee appointed by the New York State Medical Society, and second, that conditions in Massachusetts are satisfactory as they are, and do not call for any change.

Allow me to say that your quoted excerpt from the New York Committee report is simply an endorsement of the work done by the small hospitals in training nurses.

The Massachusetts Board of Registration of Nurses is in sympathy with that statement, and nowhere in this proposed amendment can there be found any expression, direct or implied, which shows criticism of, or antagonism to, the work of small hospital training schools, or the graduates of such schools.

If any one reads into the proposed amendment to the law anything of this sort, it must be the result of prejudice or suspicion.

Further, where you use the words "must get along without trained nursing when sick," and again, when you state that, "Perhaps in the future the nursing profession may provide trained services for all the people for good pay, for small pay, or for no pay at all, just as now the medical profession furnishes skilled care to all the sick," you seem to convey the impression that this proposed amendment will interfere with the practical, or experienced, or the community nurse, who has gradually become useful through her adaptation to the demands of the sick, under the instruction of the physician in charge.

Again, you misinterpret the purpose of this Bill:

The Bill only aims at registration of all nurses in Massachusetts who are useful up to their capacity. The only hardship imposed is the very small amount of time and expense involved. Under this Bill, if enacted into law, every nurse who applied, and was vouched for by a reputable physician, and such other people as might be determined on, would become registered if she showed ordinary intelligence.

The purpose of this Bill is to make it possible to keep some people from being registered, or to take away the right to act as a nurse if a person should demonstrate unworthiness.

For example, a nurse might be convicted of theft. Do you contend that she should be allowed to continue as a nurse? A nurse allowed a patient to develop an exfoliating dermatitis of the whole back and thighs through improper care and neglect. Should she be allowed to repeat this?

A nurse infected a member of a family with the gonococcus. Would you want her to repeat that process?

Nurses have aided and abetted abortionists. Should these people be let alone?

Under our present law, any nurse may do anything from gross carelessness to the most advanced criminality, and so long as she is out of jail she can continue her work.

But you say the the responsibility rests with the physician. Families often select their own nurses, for personal or financial consideration, and the doctor acquiesces unless he knows of some reason to the contrary.

Do you want each doctor to find out for himself that a nurse is incompetent and should not occupy this position of trust? Assume that a nurse loses the confidence of the people in one community, there is nothing to prevent her going to another city and starting all over again.

I agree with those who say that these illustrations are not common. I fully appreciate the faithful work

and high ethical sense of the great majority of nurses, but there are exceptions. If we eliminate the few unworthy ones, there will be more confidence in this profession.

Before dealing with this matter relating to the registration of nurses, it would seem that there are more weighty questions which should receive at least equal consideration, such as attacks which are being made upon medical practice in some of the Bills which you have not seen fit, as yet, to make note of in your editorial column. Would it not be well to devote an equal space to some of the following Bills:

Providing for the registration of chiropractors.

Providing for the registration, without examination, of physicians from without the state, and for a less fee than is required of our own physicians.

Providing for the registration of those who treat by the use of herbs. This Bill is introduced with the intent to provide for the registration of a certain person, and is, therefore, class legislation.

Again you say, "That the Board of Registration of Nurses should have supervision over the training school for nurses is a debatable point and does not correspond with the practise in the case of the Board of Registration in Medicine and the medical schools."

Permit me to call your attention to the fact that no medical school can legally confer a degree upon its graduates unless authorized by the Legislature so to do, but there is nothing to prevent any training school from conferring diplomas upon its graduates, and a well-known correspondence school does so confer them.

The proprietor of a pseudo-medical institution in this city, was recently convicted and fined for granting degrees without being authorized by the state so to do.

I would very much like to have you call attention to any other features of this Bill which you do not approve of.

Respectfully,
WALTER P. BOWERS, M.D.

A MISREPRESENTATION CORRECTED.

BOSTON, MASS., February 4, 1915.

Mr. Editor: In the February number of *McClure's* magazine, I am quoted in an article by R. H. Schauffler as backing Bernard Shaw's charges against the medical profession, except his attitude on animal experimentation. Shaw's attack is summarized in his own words, including the following sentence: "Most doctors have no honor and no conscience." Other sentences in Shaw's habitual exaggerative style follow and my approval of them all is assumed. The facts of the matter are as follows:

In the *Survey* of June 3, 1911, I wrote, at the request of that magazine, a review of Shaw's play entitled, "The Doctor's Dilemma," and said that as regards "Mr. Shaw's principal theses and in the main, I find myself heartily in agreement with him." I did not suppose that anyone would take Shaw seriously enough as to suppose that a ridiculous calumny, such as the statement that "most doctors have no honor and no conscience" would be regarded as a significant or an important remark. It should go without saying that I have no sympathy with such a statement, as I believe the medical profession to be as honorable and conscientious a body of men as any in the country. In the article on which Mr. Schauffler's misstatement of my position is founded, I summed up what in my opinion were the just offences of our profession, offences, which we all recognize and deplore. I specified such shortcomings as these,—that we do not tell patients with sufficient vigor the truth about their habits and their own responsibility for disease; that we sometimes foster cases of imaginary illness; that we sometimes perform unnecessary operations; that feesplitting and other abuses are widespread. No one, I suppose, will doubt these facts and no one will have much doubt that they will continue as long

as the doctors of the country are as miserably poor as at present. So long as the economic status of the doctor is what it is, we cannot look for much improvement in that direction.

This was Shaw's belief about the whole matter and it is mine. It is not a question of blaming anybody but of getting something done. That "something" is to diminish the number of doctors by the raising of the standards of examining boards for the license to practise medicine. This is what the medical profession can do, of itself, and do immediately. It cannot, of itself, carry out the other greatly-needed reform which I believe is coming through the more intelligent activity of hospital trustees, namely, the payment of hospital physicians for full time work and the selection of these physicians by methods that exclude favoritism and the methods of the close corporation.

I should add that I understand perfectly Mr. Schauffler's unintentional mistake in the statement of my position. He is a man for whom I have the greatest admiration and I am sure he would not willingly misrepresent anyone.

Yours sincerely,
RICHARD C. CABOT, M.D.

INFORMATION ABOUT DR. SMILIE.

BOSTON MEDICAL LIBRARY, Feb. 9, 1915.

Mr. Editor: Dr. Elton Romeo Smilie about whom inquiry was made by your correspondent in last week's issue of the *JOURNAL*, received the degree of M.D. in 1845 from the Castleton Medical College, Castleton, Vt. He apparently settled for a time in Boston, but in 1849 he removed to San Francisco. He was dropped from The Massachusetts Medical Society in 1846 with many others who had removed from the state. In 1886, according to Polk, he was living at 649 Washington Street, San Francisco. No later record of him has been found.

Very truly yours,
"ASSISTANT."

THE ROENTGEN DIAGNOSIS OF PULMONARY TUBERCULOSIS.

PROVIDENCE, R. I., Feb. 2, 1915.

Mr. Editor: In the *JOURNAL* for Jan. 28, 1915, there appears a review of "Progress in Tuberculosis," by Dr. J. B. Hawes, 2d, and Dr. P. C. Bartlett. In this paper several statements are made regarding the present status of the Roentgen diagnosis of pulmonary tuberculosis, which I do not believe it is fair to allow to stand uncorrected. One would infer from this report that the Roentgen rays have their greatest field of usefulness in the diagnosis of tuberculosis in infancy and childhood; and that, with regard to the early diagnosis in adults, they furnish merely a useful adjunct, much inferior to the other clinical methods of investigation. This is practically the same idea as is expressed in the very few scant paragraphs devoted to this subject in the recent booklet, by Hawes on "Early Pulmonary Tuberculosis."

As a matter of fact, the real situation is just the reverse. With children, the Roentgen examination usually furnishes merely helpful evidence, whereas with adults the Roentgen rays can establish definitely the presence or absence of pulmonary tuberculosis.

In infancy and childhood, the examination is largely limited to the discovery of enlarged tracheo-bronchial lymph-nodes. It is well-known that these glandular enlargements may be the result of non-tuberculous infections, such as measles, scarlet fever, pertussis, etc. Even if known to be tubercular, we cannot receive much help from the Roentgen rays in differentiating between infection and disease. This is the real problem involved, and, with respect to this, the clinical aspects of the case are the most important ones.

Of course at times other tuberculous processes may

discovered in the Roentgen examination of children's lungs, but the above are the most important findings. Indeed the entire matter of diagnosis of perculosis in children is far from satisfactory, and the Roentgen evidence is not yet standardized.

With adults, however, the situation is quite different. It is here that the Roentgen examination has its best valuable applications.

The physical conditions present in the pulmonary condition are peculiarly suitable to the early detection of pathological processes by the Roentgen rays. The Roentgen plate is merely a record of differences in density of the various tissues through which the rays pass. The greater the difference in density between adjacent structures, the more striking will be their differentiation upon the sensitive plate. In the gaseous content of the pulmonary alveoli we have a medium which allows the Roentgen rays to pass through with only the very slightest amount of absorption. Against this background of practically no resistance, pathological processes of very minute size stand out with a sufficient degree of differentiation to be recorded definitely upon the plate. We can thus show the tubercles along definite paths of invasion. Of course lesions of purely microscopic size cannot be differentiated. But clinically we are only concerned with lesions which have already gone somewhat beyond this stage.

It is thus possible to detect an area of tuberculous infiltration not large enough to furnish any definite changes with percussion or auscultation, even though employed by the most expert. Everyone must admit that there are threshold limits to the data obtainable by the usual clinical methods. Fortunately, however, the physical conditions which I have outlined above permit the threshold of differentiation by the Roentgen rays to be much earlier.

These same principles apply, it is true, to children. The difference in the pathological processes found in children renders the evidence less valuable than in adults.

These claims are not merely the "words of enthusiasts." They are the matured and calm conclusions of many able and conservative investigators, scattered throughout the world. It is of course true that this extremely early diagnosis cannot be made by superficial or careless Roentgen methods. It requires the use of the fluoroscope, several plates taken very carefully both in the antero-posterior and postero-anterior positions, especially the use of stereoscopic plates, and finally an extremely careful and conscientious study of these plates. When these methods have been carefully carried out it is not boasting to state that tuberculous lesions can be detected where the physical signs may be entirely lacking.

The clinical diagnosis of pulmonary tuberculosis is based purely upon history and constitutional reaction and may be correct in some cases, but it also frequently leads to the unnecessary treatment and segregation of non-tuberculous patients, including those suffering from syphilis, hyperthyroidism, etc. With such cases, negative Roentgen examination, when the above-mentioned methods have been carried out, can easily separate them out. This negative phase of Roentgen diagnosis is just as important as its positive aspect. The Roentgen method today furnishes the only safe method of eliminating absolutely the possibility of pulmonary tuberculosis in the adult.

The statement that "in border-line cases the Roentgen rays cannot determine the activity of a tuberculous process" does not give a fair idea of the facts. This statement may be true in some few cases of extensive tuberculosis, where there is a mixture of old and new processes and fresher ones. Here the clinical diagnosis is of extreme importance. This problem however has no place in the early diagnosis of tuberculosis. If we wish to know definitely whether there is a tuberculous process present or not. With the Roentgen method, in competent hands, this problem can be solved.

I have dwelt thus at length upon this subject as I do not think it is fair, in what purports to be a Review of Progress, to thus sweep aside, with a wave of the hand, valuable investigations that have added so much to our present diagnostic armament.

It is perhaps possible that the review represents merely the opinions of the authors, based upon their own personal experience. In that case, all I can say is that they have indeed been unfortunate in their choice of Roentgenologist.

Very truly yours,

ISAAC GERBER, M.D.

RECREATION FOR MEN IN SANITARIA.

Boston, Harvard Hotel, Feb. 3, 1915.

Mr. Editor:

In most sanatoria, men, unless very ill or very aged, have an unnecessarily stupid time, which helps morbid introspection. Women are content to sit in their rooms, read and sew. Every well-conducted sanatorium should have first, a separate recreation room for men, with magazines and games, where they can get away from the women, especially in the morning. There ought to be within easy reach light gymnastic apparatus and a shower bath for use in the morning. Secondly, it should have a billiard table, preferably of the large English type. Third, there should be a workshop with desks, stock, tools, a lathe and possibly an instructor—men who teach sloyd can be hired at a nominal salary.

If a man is confined to the house by a three days' storm, he suffers from want of exercise, and the billiard table and workshop would help very much. The writer believes that passive exercise cannot take the place of active exercise, and he thinks the professional entertainer, not Harry Lauder, but women who recite character sketches, are very tiresome.

Yours very truly,

EDWARD L. PARKS, M.D.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING FEBRUARY 6, 1915.

Dr. Lewis S. McMurtry of Louisville, Ky., and Dr. Charles A. L. Reed of Cincinnati, Ohio, have consented to become members of the Committee of American Physicians for the Aid of the Belgian Profession.

At the request of the Treasurer, the Executive Committee has arranged to have the accounts audited quarterly. The first audit will be made about the twentieth of March.

NOTICES.

Physicians visiting the city will be cordially welcomed at the following clinics on the days and hours specified.

BOSTON CITY HOSPITAL.—After January 1, 1915, public operations will be performed in the Surgical Amphitheatre each week, on Thursdays, Fridays and Saturdays, at 10 o'clock.

Thursday: First Surgical Service. Dr. Blake.
Friday. Third Surgical Service. Dr. Nichols, and
Fourth Surgical (G-U) Service, Dr. Thorndike.

Saturday: Second Surgical Service. Dr. Lund.
CARNEY HOSPITAL.—Dr. Bottomley and Dr. Mahoney will hold an operative surgical clinic every Wednesday at 9 A.M., and at the same hour on the same day Dr. W. R. MacAusland will hold an orthopedic clinic. All physicians are welcome to attend.

MASSACHUSETTS GENERAL HOSPITAL.—1. A surgical clinic Tuesday, at 12, in the out-patient amphitheatre. 2. Operations in the Bigelow amphitheatre Saturdays from 10 to 1. 3. Operations in the Surgical Building except Sunday, from 9 to 1. 4. Daily surgical ward visits at which visiting physicians will be welcome. 5. Clinic in medicine and pathology Tuesdays at 12, by Drs. R. C. and H. Cabot and O. Richardson. 6. Medical clinic Thursday at 12, by Dr. D. L. Edsall.

PETER BENT BRIGHAM HOSPITAL.—Physicians visiting the city will always be cordially welcomed at the Peter Bent Brigham Hospital.

The medical visit takes place regularly every morning beginning at 10 o'clock.

Operations are usually going on throughout the forenoon in the surgical amphitheatre.

The surgical clinic is held in the clinical amphitheatre on Wednesdays at 12.30 p.m.

The medical clinic is held in the clinical amphitheatre on Mondays at 12.30 p.m.

The medico-pathological demonstration is held in the clinical amphitheatre on Fridays at 3.30 p.m.

SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-sixth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, February 26, 1915, at 8.15 p.m.

1. "Typhoid Fever in Children," Dr. Karlton G. Percy, Boston.

2. "Homogenised Milk. Its Possible Uses in Infant Feeding," Dr. Maynard Ladd, Boston.

3. "Luetic Bursopathy of Vernieuil. Report of a Case. Congenital Type," Dr. William P. Coues, Boston.

4. "Some New Symptoms in Amaurotic Family Idiocy," Dr. Isador E. Coriat, Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*

RICHARD M. SMITH, M.D., *Sec'y.*

THE HARVEY SOCIETY.—The ninth lecture of the series will be given at the New York Academy of Medicine, 17 West 43rd street, on Saturday evening, February 27th, at 8.30 p.m., by Prof. R. R. Bensley, University of Chicago. Subject: "Structure and Relationships of the Islets of Langerhans and Criteria of Histological Control in Experiments on the Pancreas."

APPOINTMENTS.

ARIAL W. GEORGE, M. D., Boston, has been appointed Assistant-Professor of the Department of Roentgenology, at the Tufts College Medical School. Dr. George has also been appointed on the consulting staff of the Carney Hospital.

DR. GEORGE BURGESS MAGRATH has been reappointed medical examiner for the County of Suffolk, Mass.

CORRECTION.

In the schedule of lectures in the School for Health Officers, published in the issue of the JOURNAL for Jan. 28, Dr. Harrington's third lecture on School Hygiene should have been announced for Feb. 24.

RECENT DEATHS.

DR. WILLIAM DUGAN KELLY, of Boston, died on February 9, of septicemia, apparently acquired by infection from a patient with acute tonsillitis. He was born at Lamont, Ill., in 1880, and removed to Boston as a boy, graduated from Boston Latin School and from the Harvard Medical School, receiving the degree of M. D. in 1903. Since 1904 he had served as a school physician for the Board of Health in this city. He was a Fellow of the Massachusetts Medical Society, a member and former president of the Boston Medical Society and a member of the Boston Medical Library. He was a member of the staff of Mt. Sinai Hospital, of the Sunnyside Day Nursery and of the Milk and Baby Hygiene Clinic at the Elizabeth Peabody House. He was unmarried.

DR. AMOS HAGAR PEIRCE, a Fellow of The Massachusetts Medical Society, died at his home in West Newbury, February 9. He was a native of Lincoln Mass., and was a graduate of the Boston University School of Medicine in 1882.

EXPERIMENTAL USE OF MAGNETISM FOR LOCATING NEEDLES IN THE TISSUES. A PRELIMINARY REPORT.*

BY GEORGE H. MONKS, M.D., BOSTON.

IN the days before the x-rays were used for locating needles in the tissues of the body, the surgeon had often little to guide him except such information as was furnished by the history of the case. In the event that a needle, or part of a needle, was said to be in the tissues there was often not even an indication in the skin as to the position of the wound of entrance. Occasionally, to be sure, the needle could be felt through the skin, but such cases were rare. The surgeon could not even be sure, except from the statements of the patient, that the needle was still within the tissues, or that it had been there at all.

The coming of the x-rays has been a blessing in that it gives incontrovertible evidence (1) that the needle is, or is not in the tissues, and (2) that, if buried there, it is in such and such a position, and is in relation to such and such structures. In spite of all this, however, it sometimes happens that the surgeon finds the needle only after a long search, or he does not find it at all. It is quite possible that the x-ray plate has not been correctly interpreted, or that the needle has changed its position. Such being the case, it is obvious that, if any expedient can be found that will give further assistance in the

search for the needle, it may at times be distinctly helpful.

More than a year ago it occurred to me that the surgeon might be aided very materially in his search for a buried needle, if magnetism could be called to his assistance, and since then I have made from time to time a number of experiments to determine if such assistance were possible. After a good deal of experimenting I came to the conclusion that, in order to enable the surgeon successfully to employ magnetism in this way, two things are essential:—

- (1) He must magnetize the needle, or the needle fragment, which is in the tissues, and
- (2) He must locate this needle by means of a magnetized indicator of some kind.

After devising a number of different methods by which both of these requirements could be met, I finally reached the conviction that the simplest way was to magnetize the buried needle by means of a magnet, preferably an electro-magnet, applied as near as possible to the supposed resting place of the needle; and that the best way to find this needle after it had been magnetized was by means of a minute compass, or by the use of a highly magnetized steel needle suspended from a fine silk thread. I also used with success a very fine horse-shoe magnet made from the smallest watch-spring I could find.

I have not as yet had the opportunity of trying this method on the living subject, but, as I have used it successfully under many different conditions, I have a reasonable expectation that it will work with equal satisfaction in actual operative work. I have succeeded in magnetizing a fragment of a needle through glass, wood, felt, and various other substances, of different thicknesses up to one-half inch, and even occasionally

* Received for publication January 30, 1915.

more. I have also on several occasions found a needle through an incision into a piece of meat, the needle having previously been hidden in the meat by another person without my knowing its position.

The procedure is as follows:—

(1) The buried needle is magnetized by passing a magnet over the locality where this needle is supposed to be. The best results are obtained when the long axis of the magnet is in the same line as the axis of the needle.

(2) The examining needle (suspended in the middle from a fine silk thread) is then slowly passed over the same locality.

In the event that it passes over the buried needle.—provided that needle is not too far away from the surface—one end or the other of the examining needle will be attracted and will dip in the direction of the buried needle somewhat in the same manner as the “divining rod” is said to do, when that rod is brought to a place on the ground under which water can be found.

As the buried needle, after it has been magnetized, has two poles (N and S), and as the examining needle has also two poles (N and S), it follows that (according to the physical law, that “like magnetic poles repel one another; unlike poles attract one another”) the N pole of the examining needle is attracted to the S pole of the buried needle, and the S pole of the examining needle is attracted to the N pole of the buried one.

At the earliest opportunity I shall make the effort, in this manner to locate a buried needle, either from the surface of the body or from a wound.

lorus in infants, constriction or pulling out of place of the organs by adhesions between the stomach and the adjacent organs, as adhesions to the gall bladder, or to the caecum, or peritoneum, and rare conditions, as sarcoma of the stomach, syphilitic disease of the stomach tissues, tuberculosis of the stomach.

2. Conditions of functional disturbance of the stomach not due to disease or disturbance elsewhere in the body, as hyperacidity pure and simple, not secondary to ulcer or gall bladder trouble, etc., hypoacidity of the stomach not due to cancer or gastritis, or disease elsewhere, hypomotility of the stomach, not due to constriction of the pylorus or malformation or adhesions.

3. Disturbances of the stomach occurring as associates of general diseased conditions, as typhoid, pneumonia, nephritis, tuberculosis, debility, nerve prostration.

4. Conditions of disturbance of the stomach function or condition, when the symptoms noted by the patient appear to be in the stomach, where the actual disease or disturbance is located elsewhere. To this class belong such conditions as the vomiting of pregnancy, the gastric crises of tabes, the manifestations of gastric symptoms, as distress in the epigastrium, raising of gas, even vomiting, seen in conditions of gall bladder trouble, appendicitis, cancer of the intestine, adhesions involving the intestine, simple constipation, conditions of acidosis, uraemia, liver trouble, mesenteric thrombosis, cases of cerebral tumor, head injury, cases of eye trouble, heart disease, angina pectoris, arteriosclerosis.

In the diagnosis of any case of stomach disturbance, or any case where the patient comes to him complaining of stomach symptoms, the physician must at the start consider in a general way the whole ground described above, in contemplating the possible causation of the stomach symptoms, or adjudged stomach symptoms, present.

The so-called stomach case may be a case of gall stones, or appendicitis, or heart trouble, or syphilis, intestinal adhesions, constipation, nerve debility, or it may be a real case of organic stomach trouble, or of functional stomach trouble.

As first aid in the diagnosis of the case, the physician has the history and record of symptoms as outlined by the patient. Following this is the finding of the general physical examination, the record of auscultation, percussion, palpation, of the blood and urine examination, etc.

In addition to these two features of clinical examination utilized in the study of all cases in medicine, we have in the study of stomach troubles, or of cases with adjudged stomach symptoms, three extra special methods of examination; the examination of the stomach contents as obtained by the use of the stomach tube, the investigation of the stomach by the x-ray

THE STUDY OF DISTURBANCES OF THE STOMACH.

BY H. F. HEWES, M.D., BOSTON.

[From the Clinic of the Massachusetts General Hospital.]

THE varieties of conditions included in the general classification of stomach trouble, untoward condition of disturbances of health or comfort in which the patient places the symptoms or most marked symptoms in the stomach, may be divided into four classes:

1. Conditions of actual organic disease of the tissues of the stomach, or anatomical deformities of the organ, or of the organs representing a direct continuation of the stomach, as the esophagus and duodenum. In this class are included ulcer of the stomach, ulcer of the duodenum, cancer of the stomach, gastritis, *i. e.* acute and chronic, atrophy of the stomach cells, actual inflammation of the mucous membrane, cancer of the esophagus, diverticulum of the esophagus, gastroptosis, congenital deformities of the stomach as narrowed or imperforate py-

bismuth method, and the examination of the feces.

By the employment of this full clinical procedure, including all these methods of examination, in his cases with stomach symptoms, the physician should, in the great majority of cases, be able to reach a very definite conclusion in regard to the nature of the disease or disturbance giving rise to the symptoms in the case.

Frequently the utilization of the full method of investigation is not necessary. In many cases the result of the initial method of study, the study of the history record and findings of the general physical examination may suffice entirely for the making of a diagnosis. Thus the definite finding of appendix trouble, or cord syphilis, or angina pectoris, or nephritis, or tuberculosis, may make a special examination by the special methods of stomach investigation unnecessary, the symptoms, even though they appear to be of the stomach, being accounted for by the definite disease discovered elsewhere.

On the other hand, frequently the study of these records may suffice only to rule out certain outside conditions, and the special study of the stomach be necessary for the elucidation of the case.

So that to be equipped for work in the study of stomach cases the physician must be conversant with all these methods of examination, and with the significance of the findings revealed by them, for the interpretation of the case.

The first method of clinical study, the study of the record of the history and symptoms as described by the patient is of course of great value in connection with the diagnosis of stomach cases. Frequently we learn from this alone, if the record is carefully taken, that what appeared to be a stomach case is not that at all, that the pain, etc., described is not in the stomach but in the lower abdomen, that what the patient means by stomach trouble is constipation, or diarrhoea, and so on.

Frequently, on the other hand, this record is so typical that it tells us without further investigation that we have a disease of the stomach and the nature of the disease.

There are certain typical records found in some cases of definite stomach diseases, as ulcer or cancer, which are practically pathognomonic in themselves or nearly so.

Such are, for example, the record of the vomiting of large amounts of blood found in some cases of fresh ulcer of the stomach; the record of accumulation of contents in the stomach with final vomiting of large amounts, found in cases of ulcer or cancer involving the pylorus and causing stasis; the records of continual vomiting combined with great loss of flesh and strength seen in some cases of cancer, and the long histories of intermittent spells of the stomach symptoms of hunger pains, pyrosis, etc., found in some cases of chronic duodenal ulcer.

But in the majority of cases even of organic stomach trouble the record of the history alone

is not diagnostic. Many marked cases of ulcer or cancer have a symptomology of a mild type, much less suggestive of serious trouble than many records of functional stomach trouble, or of stomach trouble secondary to outside conditions as gall stones, appendicitis, syphilis, or nerve debility.

Also these outside conditions may give a picture of stomach symptoms quite as severe in type or of the same type as those recorded above as typical symptomatologies of ulcer and cancer.

On the whole, the history of symptoms, is the least reliable of all methods of investigation for the diagnosis of disturbances with stomach symptoms. I make it a practice never to make a positive diagnosis of stomach trouble, or to advise operation, on a record of a case consisting of the history alone, save possibly in cases with a substantiated record of the vomiting of blood.

To make such a diagnosis we must have some positive clinical finding by physical examination, tube examination, x-ray examination, one or all, as a blood finding, a hypersecretion finding, a stasis finding, a gastritis finding, a tumor, or a positive x-ray picture for the diagnosis of organic stomach trouble, or the absence of abnormality in such findings to rule out organic stomach trouble.

The history record, however, though not absolutely reliable in itself, is of the greatest value taken in connection with the other clinical findings.

And much of its value depends upon the skill of the physician in obtaining from the patient a correct history record, and correct impression from this record. A record which taken in one way reads like a record of stomach trouble, may when taken correctly read as a record of constipation, or gall stones, or renal stone, or heart disease, or nerve debility.

The second method of investigation, the full physical examination, may be of great importance.

It may, in the first place, locate the seat of the disease which is causing stomach symptoms or so-called stomach symptoms, as elsewhere than in the stomach, as for example an appendicitis, or heart trouble, an anaemia, a kidney disease. Often it is necessary according to the nature of the case to supplement the routine physical examination, of inspection, palpation, percussion, urinary and blood examination, with special examination, as a Wassermann test, a test of the spinal fluid, a feces examination, a sputum examination. The meaning of stomach symptoms may appear in a very different light in a case with a positive Wassermann test than in a case without this reaction.

The third method of investigation, the examination of the gastric contents, both the fast-ing contents, and the test meal contents, as obtained by the use of the stomach tube, is of great value in connection with the study of stomach cases.

Frequently in cases of actual organic disease or of definite functional disease of the stomach it gives us an absolute diagnosis. Often by a negative finding it serves to rule out the existence of certain definite stomach diseases.

The routine of this examination consists of:

1. The examination of the fasting contents obtained after a twelve-hour fast.

This contents is inspected or tested as to its quantity, the presence of food residue, the presence of blood, either fresh blood or a chemical blood test, the presence of free HCl and the character of the specimen and its sediment.

2. The examination of the test meal contents, the contents obtained one hour after the ingestion of an Ewald test meal.

This contents is tested for free HCl, and, if this is present, a quantitative estimate of total free HCl is made. If free HCl is absent, an estimate of total acidity and a test for the presence of ferments may be made.

It is not necessary to make this full routine tube examination on all cases, as a part of it, the study of the fasting contents, for example, may make our diagnosis. But it is often necessary to make a full examination.

The findings by tube examination which are of most importance for diagnosis are:

1. A positive blood finding in the fasting contents, fresh blood as noted by inspection or a positive blood test by chemical method. A few shreds of blood may sometimes be obtained in a normal stomach as the result of the action of the tube, but any considerable amount of blood, or a test for blood in a contents showing no fresh blood, is always significant of the existence of some pathological condition of the stomach. It may be esophageal varices; it may be a stomach diseased as part of the disease pernicious anemia or purpura or of alcoholism; it may be ulcer or cancer, but it is always a sign of bleeding, which is pathological. There are the above rare cases of blood in the stomach besides ulcer or cancer, and there are rare cases of bleeding of unexplained cause, but in the great majority of cases where bleeding is present in the stomach it is due to ulcer or cancer or duodenal ulcer, and this blood finding by tube examination is therefore a very important fact in connection with the diagnosis of these conditions.

Certainly we can say that a record of repeated blood findings in the gastric contents is strong suggestive evidence of the presence of ulcer or cancer. The finding is of particular importance when supported by a positive blood finding in the feces.

2. A twelve-hour stasis finding in the fasting contents, a large amount of contents containing food, obtained 12 hours after the ingestion of a meal.

This is pathological and means obstruction of the pylorus by cancer or ulcer, or, rarely, by some other cause as adhesions or tumor outside pressing upon and obstructing the gut.

We may get lesser degrees of hypomotility in functional conditions and rarely in conditions of extreme debility from any disease, intestinal paralysis from peritonitis, total loss of function in moribund conditions in any disease, the phenomenon of a twelve-hour stasis may occur. But otherwise it almost invariably means a cancer or ulcer of the stomach and is a very positive diagnostic finding.

Conditions of less degree of retardation or stomach emptying doubtless occur in atonic stomachs from other causes, ptosis with dilatation, for example. Often we may get a six-hour bismuth stasis in other conditions, but a twelve-hour food stasis means, as stated, organic disease of the stomach.

As between cancer and ulcer as a cause of stasis, other factors of the examination, as the presence of blood, the presence of free HCl, may help discriminate. Stasis simply means one of the two, with the exceptions noted, and the other factors with the history and x-ray examination may help us to determine which.

3. The finding of a fasting contents showing hypersecretion, that is, an abnormal quantity of contents—50 to 100 c. c.—consisting of pure fluid containing free HCl, but no food residue. The quantity of fasting contents in the normal may run as high as 30 c. c. We may get abnormally large amounts of contents in gastric stasis or chronic gastritis, or in hypersecretion. Stasis contents show food, gastritis contents show mucus or a marked cellular sediment. Hypersecretion is simply a large amount of contents of normal character with no food, and not a mucous content like gastritis.

Hypersecretion may be a sign of simple functional hyperacidity of the stomach, a well recognized stomach malady, or it may be an associate of ulcer of the stomach or duodenum or of adhesions to the stomach or duodenum. It is, therefore, simply a sign of an abnormal stomach malady, suggestive, taken with other findings, of ulcer, but often meaning simply a functional hyperacidity.

As a rule a high percentage of free HCl in the test meal contents is associated with it.

4. A finding of a mucous contents or a contents containing many stomach cells in mucus.

This phenomenon is characteristic of the disease chronic gastritis. Chronic gastritis may be an associate of cancer or it may occur by itself. It is common in alcoholism and cirrhosis.

5. A finding of an abnormal cellular sediment in the fasting contents.

This finding is often made in cases of cancer or ulcer. It is, of course, also made in chronic gastritis.

It is not diagnostic but often suggestive with other signs. Normally the sediment of the fasting contents may contain a few cells or many leucocytes—but it does not contain numerous stomach cells (cylindrical epithelial cells). This latter finding is often present with cancer of

the curvature, sometimes with chronic ulcer of the wall.

6. The presence of free HCl in the fasting contents is the rule, but absence of free HCl is not a sign of abnormality, as absence of free HCl in a test meal contents would be. A very high percentage of free HCl is often found in hypersecretion and ulcer cases.

The findings of importance in the test meal contents are as follows:

1. The presence of free HCl.

Normally free HCl is always present in a contents obtained one hour after an Ewald test meal. Absence of free HCl means an abnormal condition. This may be an associate of cancer or chronic gastritis, but it may exist as a purely functional condition. Absence of free HCl is important in connection with a diagnosis of cancer taken with other findings suggestive of cancer, as stasis or a blood finding or a tumor. But alone it has no special significance in this way. Presence of free HCl in a test meal contents is often found with cancer and almost always found with ulcer.

2. The quantitative estimate of free HCl.

In the normal after a test meal the amount of free HCl varies. Its maximum normal is about 0.145%. Amounts above this figure mean hyperacidity. This is found in the condition known as functional hyperchlorhydria. It is found as an associate of ulcer.

3. The tests for ferments may be of importance in determining the existence of the diseases achylia gastrica or atrophy of the stomach. Here we get no free HCl and no ferments. In the average case of hypoauidity the ferments are present.

Tube examination is an indispensable adjunct of the study of conditions of stomach disease. The evidence obtained by this method when of positive character is much more definite as to diagnosis than the evidence obtained by the record of symptoms.

Negative evidence by tube examination does not rule out the existence of organic stomach or duodenal disease. Thus conditions of chronic duodenal ulcer often exist with a normal tube finding. Cancer or ulcer of the stomach may have a normal finding, often a finding which, though abnormal, is not definitely diagnostic of these conditions.

But positive evidence by this method is often absolutely diagnostic and never, like apparently good evidence, supplied by a history record or an x-ray examination, misleading in a positive direction.

The fourth method of examination, the study of the stomach by the x-ray bismuth method, is of great value for the diagnosis of disease of the stomach.

It is particularly useful for the diagnosis of cancer of the stomach or ulcer of the stomach and duodenum. Thus Carmen states that 93% of ventricular cancers under his examination were recognized by x-ray examination, that is,

an x-ray finding suggestive of cancer was found in this percentage of cases of cancer.

In 7% of the cases of cancer the condition was not recognized.

In ulcer of the stomach, 65% of the cases were recognized by x-ray, the remaining 35% not giving definite signs.

In duodenal ulcer 135 cases out of 190 were clearly recognized by x-ray examination.

The methods of study by x-ray bismuth are two in number, the fluoroscopic method and the radiographic method. In any given case either method may give equally definite finding, but of the two the fluoroscopic method is in my experience the more useful.

Evidence of the existence of ulcer or cancer of the stomach or duodenum by x-ray examination appears in three ways:

1. As an abnormality in the outline of the shadow of the stomach and duodenum.

2. As an abnormality in the peristalsis over a portion of the wall of the organs or of the peristalsis of the stomach generally, independently of the site of the lesion.

3. In certain cases, as, for example, those in which the lesion causes some obstruction or interference with the regular expulsion of stomach contents, a third sign may appear, namely, an abnormality in the discharge of bismuth from the stomach or duodenum, showing sometimes, as a stasis of bismuth in these organs for a longer period than normal, sometimes as a more rapid initial emptying of the stomach than normal.

In conditions of chronic ulcer involving the stomach wall in any location above the pylorus, not obstructing this opening, we find in well-marked cases, an absence of peristalsis over a portion of the stomach wall where the lesion is located. Peristalsis comes down to this point, is checked here, skips this portion, or is irregular here, and goes on below it.

In well-marked cases where, for example, the ulcer is a penetrating ulcer or where much contraction of the wall from scar tissue is present, we find also an irregularity in the outline of the stomach corresponding to this area of disturbed peristalsis. Sometimes a crater filled with bismuth can be seen at this point. Sometimes the shadow appears as a diverticulum, a deep invagination or projection of the wall, with sometimes a shadow of bismuth outside the outline of the stomach. In some cases we get an hour-glass shadow evidencing contraction of the wall by ulcer.

In addition to this check in peristalsis or irregularity in outline at the seat of the ulcer, the whole stomach often shows in these cases, a general abnormality in peristalsis, consisting of a very deep and vigorous peristalsis most marked above the seat of the lesion, but extending over the whole stomach.

Often on the wall opposite the seat of the ulcer a marked spasm is seen, a tendency to

tonic contraction at the point, known as an incisura.

In a case of ulcer of the stomach wall above the pylorus all of the above phenomena, *i. e.* local disturbance of peristalsis in a limited area, local irregularity in outline, generally increased peristalsis, incisura opposite the ulcer, may be present.

In other cases some one or two of the signs only may be present, as for example, simply an area of checked peristalsis, or simply an incisura in a portion of the wall suggesting the presence of an ulcer on the opposite wall.

In the cases with many signs or marked signs of abnormality, as, for example, cases with a crater or a diverticulum, or a marked irregularity in outline in a portion of the wall, we consider that we have fairly definite signs of an ulcer, or of an organic lesion, either ulcer or cancer.

It must be emphasized, however, that even such emphatic pictures can be caused by other conditions, as, for example, a condition of adhesions attached to the stomach wall, adhesions from the gall bladder, or peritoneal surface of the abdomen. Adhesions may cause an actual irregularity in the outline of the stomach wall. Often they cause irregularity in peristalsis over a portion of the wall, or general abnormality of peristalsis.

In the cases of the finding of so-called moderate signs of disturbance as, for example, cases showing simply an incisura as an abnormal sign, we feel that the finding may be evidence of an ulcer, but that it is not definitely diagnostic of this lesion, as other causes, adhesions, or reflex spasm from gall bladder trouble, from cord syphilis, or from simple nerve causes, may give this finding.

Ulcer of the stomach wall not at the pylorus may also cause some disturbance in the emptying of the stomach, showing in the presence of stasis of bismuth in the stomach for an abnormal period, a six-hour bismuth stasis, for example, but this finding, though important in connection with other abnormal findings, is not in itself a very definite sign of ulcer. Ulcers of the antrum do often cause pylorospasm as an abnormality. Sometimes, also, there may be as a result of the excessive general peristalsis associated with the ulcer, an abnormally active initial emptying of the stomach.

Ulcer of the stomach wall may be present without showing any abnormal signs by x-ray examination, and, as stated, not infrequently ulcer though showing some abnormality does not show definite enough signs to allow of absolute diagnosis as a result of study of this method. Fresh bleeding ulcers often show no definite signs, also superficial chronic ulcers. Penetrating ulcers, or ulcers causing much contraction of tissue, as a rule show very definite signs of abnormality.

To summarize then, though we cannot always diagnose ulcer of the stomach wall by this

method, even where ulcer exists, and may even find no signs of abnormality in such cases, we can say that the method gives us a means of determining the presence of ulcer in many cases. A negative finding cannot be taken as absolute evidence of the absence of ulcer.

Ulcer of the stomach involving the pylorus gives in practically all cases definite signs of abnormality by x-ray examination. This picture differs in many features from that given by ulcer of the wall in location other than at the pylorus, just described. Here we find:

1. Absence or irregularity of the sphincter.
2. Abnormally deep and vigorous peristalsis of the stomach.
3. Sometimes irregularity of outline in pyloric region.
4. Retention of bismuth in the stomach for a longer period than normal, a nine-hour residue, a twelve-hour residue, a twenty-four-hour residue, according to the amount of obstruction caused by the lesion.

Often no bismuth can be seen entering the duodenum and no duodenal cap is made out. It must be borne in mind, however, that similar findings may be present from other causes, as, for example, cancer of the pylorus, adhesions involving the pylorus or duodenum. Cancer as a rule, does not show the vigorous peristalsis of the stomach seen in ulcer, but it may do so. Otherwise the signs are often the same. Adhesions may give the whole picture as described for ulcer.

The findings by bismuth x-ray examination of duodenal ulcer are as follows:

Ulcer of the duodenum involving the pylorus, or causing obstruction of the pylorus, shows the same signs as ulcer of the stomach involving the pylorus just described.

Ulcer of the duodenal wall located below the pylorus, but not causing actual narrowing of the opening shows, as a rule

1. Irregularity of the duodenal cap.
2. Extra deep and vigorous peristalsis of the stomach.
3. Some retardation in the emptying of the stomach, *i. e.* a six-hour bismuth stasis. Often this is the whole picture of this condition.

In some cases an actual irregularity in the shadow of a portion of the duodenal wall is seen in addition to the general irregularity of the cap—sometimes a crater or diverticulum with bismuth outside the shadow of the duodenum. Sometimes the bismuth appears to remain there and not pass on normally. Sometimes there is marked pylorospasm. Often in duodenal ulcer there is initial hyperactive emptying of the bismuth from the stomach due to the extra stomach peristalsis associated with this condition. Often with duodenal ulcer both below the pylorus or involving the pylorus, the pylorus of the stomach is further to the right than normal.

Duodenal ulcer well below the pylorus may

exist without any abnormal signs by x-ray or without signs which are definitely diagnostic of this lesion. Fresh bleeding ulcer may show no signs; chronic ulcer as a rule shows signs which are at least suggestive.

Adhesions involving the duodenum may give a picture exactly similar in all respects to that considered typical of duodenal ulcer.

Some of the signs, as pylorospasm, a six-hour residue, abnormality in peristalsis, may occur in gall bladder trouble, appendicitis, or in tumors in the abdomen outside of the stomach.

Cancer of the stomach wall located above the pylorus shows by x-ray examination:

1. A portion of the stomach wall where peristalsis is absent or irregular.
2. An actual irregularity in the shadow of the wall, that is, a finding similar in many ways to those found in chronic ulcer of the wall.

In many cases the irregular shadow is of such a character that it is fairly typical of cancer, as distinguished from ulcer. This is, however, not always the case.

The peristalsis of the stomach generally outside of the region affected is as a rule sluggish. In this way the picture of cancer differs from the usual picture seen in ulcer where the peristalsis is apt to be extra vigorous. However, in both cancer and ulcer general peristalsis may be normal. Sometimes in cancer we see actual craters filled with bismuth.

Cancer involving the pylorus shows:

1. Absence or irregularity of the sphincter.
2. Abnormally long retention of bismuth in the stomach, according to the extent of obstruction.
3. Marked irregularity of outline of the stomach shadow at the location of the lesion.
4. Peristalsis of the stomach above is apt to be sluggish as contrasted with that seen in ulcer of the pylorus, but this distinction is not universal. If obstruction is marked no duodenal cap is seen.

The distinctions in the pictures of cancer and ulcer of the stomach both of the curvature and of the pylorus are very clear in some cases, but in others not definite. Where cancer is at all extensive, the irregular shadow is of a very different type than that of ulcer. As stated, peristalsis of the stomach is apt to be more sluggish in cancer.

With cancer at the pylorus the closure is often less absolute and the spasm seen in ulcer lacking.

The findings by x-ray examination seen in connection with the condition of adhesions involving the stomach and duodenum have been to a certain extent described in connection with the description of the findings in ulcer.

As stated, adhesions involving the stomach wall may give absolutely the picture considered typical of ulcer or cancer, viz. an area of absent peristalsis, often an irregularity of outline. In-

cisura may be present. General peristalsis may also be abnormal, showing sometimes increased peristalsis, occasionally sluggish peristalsis. Sometimes the stomach is definitely drawn out of position.

Adhesions involving the duodenum may give every sign of duodenal ulcer, absence or irregularity of the cap, increased and deep peristalsis above, a six-hour bismuth stasis, sometimes absence of sphincter, and a nine-hour stasis.

The exact value of the x-ray method of investigation of the stomach, as a means of diagnosis of stomach disease, cannot at the present time be accurately estimated. This fact can be determined only after a study of a large number of cases in which a record of x-ray examination and of the actual disease present as revealed by operation, or postmortem, or other definite findings, are obtained. The method has at present been under use too short a time to give sufficient data for a final judgment as to its accuracy throughout the whole field of the diagnosis of stomach disease. We can, however, from present knowledge, reach some very definite conclusion in regard to its value for this work.

The x-ray bismuth method of examination is useful for the diagnosis of the following diseases of the stomach and duodenum: ulcer, cancer and adhesions involving the organs. It is also useful for the determination of the size and position of the stomach.

In some cases the x-ray finding is of so definite a type that a diagnosis of the disease, as ulcer or cancer, can be made with assurance from this finding alone. This is true in cases where the lesion is at the pylorus.

In other cases the finding is definite enough for a diagnosis of the existence of one of the three organic stomach lesions described: cancer, or ulcer, or adhesions, but not pathognomonic enough, taken alone, to distinguish which of the three is present.

In the majority of cases in which the x-ray examination gives suggestive evidence of the existence of one of these conditions, however, the finding cannot, even if of a fairly definite type, taken alone, be considered as absolute evidence for the diagnosis of any one of these three separate conditions.

Either we have evidence perhaps fairly diagnostic of the existence of some organic trouble, that is one of the three conditions, but not distinguishing which, or findings which while suggestive of the existence of one of the conditions, are of a type which may be found in conditions other than organic stomach disease.

I have seen conditions of exactly similar findings in cases of cancer and ulcer. I have seen adhesions involving the stomach or duodenum give the exact finding seen in marked cases of ulcer and considered as typical x-ray finding of ulcer. I have seen cancer diagnosed where adhesions were the only pathological finding.

And most of all, I have seen findings similar to those found in proven cases of cancer and of ulcer marked findings considered typical of these conditions, where no organic lesion of the stomach was present, as proven by operation and opening of the stomach.

I have seen sometimes a whole typical picture of, and often some of the signs of, organic stomach disease, as incisura, pylorospasm, a six-hour residue, in gallstone cases, appendix cases, syphilis of the stomach, syphilis of the cord.

The method is of very great value in connection with the diagnosis of the existence of the stomach conditions, but as a rule positive diagnosis of the existence of such conditions should never be made by x-ray examination alone, unconfirmed by other clinical findings, as tube findings, or feces findings, or at least by a very typical history.

This is a point which has been emphasized to most of us by costly experiences. Abnormal x-ray findings, while perhaps more constantly positive, in conditions of ulcer and cancer, that is, more universally present in the whole run of cases, than other clinical findings, as tube findings or feces findings, have the one deleterious feature, that they may be present, where no organic stomach lesion exists. Tube findings, for example, may show no definite abnormality in many cases of gastric ulcer, where x-ray findings give positive evidence, but the former never give definite, so-called diagnostic findings, where no lesion exists.

I call particular attention to this misleading quality of the x-ray method because it is a habit today among many physicians and surgeons to utilize x-ray examination to the exclusion of the more thorough method of investigation, and to abide too much by the x-ray finding or its interpretation in diagnosis.

The value of x-ray examination as a means of excluding by negative findings the presence of organic lesion, cannot be absolutely determined, since we have no way of judging at present exactly how many cases of cancer or ulcer we overlook.

We do know, however, that both cancer and ulcer may be entirely overlooked by the method. This is particularly the case with fresh bleeding ulcers, diagnosis proven by haematemesis, or tube findings, or stool examination, or by later operation, and is undoubtedly true of early stages of cancer. I have seen cases of ulcer showing blood by tube, or blood by feces, later operated upon and found, with negative x-ray findings upon repeated trials. And I have seen cases with symptoms showing a negative finding, return within a year and show a positive finding of cancer both by x-ray and operation findings.

I do, however, take a good deal of satisfaction in the use of the method for probable exclusion of cancer or ulcer in certain cases, as, for example, cases with tube findings of chronic gastritis associated with hypochlorhydria where it is important to determine whether the gastritis

finding is an associate of cancer or not, or cases with hypersecretion and hyperchlorhydria where it is important to determine whether we are dealing with simple hypersecretion or hypersecretion associated with ulcer.

Negative x-ray findings are not absolutely exclusive in such cases, but they are reassuring.

The use of the x-ray method of investigation in the study of stomach cases is not, of course, necessary in all cases, since a positive diagnosis is often made as a result of the study of the other routine methods of examination without resort to this ordinarily more expensive method of investigation. It is necessary in all cases where the findings by the other methods indicate or strongly suggest the presence of some serious pathological process, without giving evidence for positive diagnosis of the condition.

How far we should go in the employment of the x-ray method of study in the investigation of these cases with stomach symptoms not showing any definite evidence of the existence of disease elsewhere, as gall stones, appendix, etc., as a cause of symptoms, and not showing a definite abnormality in the tube finding for diagnosis of stomach disease, is a point which cannot be settled by any general rule. We should like an x-ray examination in all such cases, partly because x-ray examination does in many cases give definite evidence of a pathological process where other methods of examination fail to do so, and partly because, though absence of x-ray findings does not absolutely rule out the presence of cancer or ulcer, it gives us one more argument for excluding these conditions. But under present circumstances we cannot have the desideratum.

(To be continued.)

PLASTIC SURGERY IN PROCIDENTIA, WITH REPORT OF TWENTY-FIVE CASES.*

By FLORENCE W. DUCKERING, M.D., F.A.C.S., BOSTON.

Attending Surgeon, New England Hospital for Women and Children, Roxbury, Mass.; Attending Physician, Pope Dispensary.

As we get some degree of prolapsus in practically all lacerated and over-stretched cases which come to us for repair, we will leave the first degree out of this paper, and consider only the cases of complete or incomplete procidentia, where there is an extrusion of cervix or fundus from the vulvo-vaginal opening with, or without, eversion of the vaginal walls.

Four of my cases occurred in single women with a nulliparous cervix and a stretched, rather than a lacerated, condition of the vaginal outlet. I am thoroughly convinced after a careful study

* Read before the New England Hospital Medical Society, Nov. 19, 1914.

of this subject, that the shape and length of the cervix is the most important factor in the great majority of cases, and that this is often accounted for by heredity. Nowhere in the literature can I find the statement that this condition runs in families, which apparently is principally due to the length and shape of the cervix, and contributed to, no doubt, by slender ligaments and perineal muscles.

I have in mind two sisters, both nulliparae, one of them being unmarried, who came to me with a complete procidentia and marked eversion of the vagina. The unmarried sister had a fibroid, which added weight and pressure, and after an abdominal hysterectomy, where the cervix was removed by special request, there was an eversion of the entire vagina, probably partly owing to the fact that I did not fasten the vaginal wall to the round ligaments at the time of the first operation for hysterectomy, and after six months the prolapse recurred suddenly during a fit of coughing. I did a plastic operation, which up to this time is entirely satisfactory. Both these cases were long past the menopause; the second sister, being too old and frail for operation, is able to wear a pessary.

In another of my cases there is a history of a patient's mother and sister having the same trouble, and in still another the patient's mother has "falling of the womb" and two sisters have some trouble. In married women, most of my cases gave a history of normal labors. Several had only one child, and it seemed in their case a cause of one-child sterility, due probably to the posterior position of the uterus. In almost all the cases the uterine canal was longer than normal, often no doubt brought about by increased weight and subsequent stretching and elongation of the supra-vaginal cervix, but many of them, I am firmly convinced, were congenital. We all know that certain mental and physical characteristics may be transmitted by heredity. Why not, then, the shape and strength of the pelvic viscera? The shape of the bony pelvis also varies in patients and its relation to the abdominal axis, causing a vast difference in intra-abdominal pressure. The uterus is a freely movable body, and its relation to the vaginal canal varies, being chiefly regulated by the length and strength of its attachments, especially the anterior, round, and utero-sacral ligaments. Short posterior ligaments predispose to retro-positions, and are an important factor in procidentia. A short anterior lip, in many cases due to a low implantation of the anterior vaginal wall, is apt to maintain its axis in the pelvis by an antelexion. Retrocession may complicate either condition, and gradual descent from intra-abdominal pressure will follow, if it comes on the upper, instead of the posterior, surface of the fundus. Increased weight of the uterus, as in sub-involution or tumors, tends to stretch and weaken the round and broad ligaments, and permit descent. Increased intra-abdominal pres-

sure, from whatever cause, is an important factor, especially if the relation of the axis of the uterus to the pelvis has been changed, so that the pressure is exerted in the direction of the outlet. This varies to a limited degree by a full bladder or rectum, and is aggravated by straining, coughing, and lifting; indeed, the latter are often given in the history as active causes. Overstretching from repeated pregnancies with lacerations of the birth canal is one of the most common causes of procidentia, though the patient may have no discomfort or knowledge of the fact for years, frequently not until after the menopause. We often see severe lacerations of the cervix and perineum with cystocele and rectocele, but if the uterus is in the right axis to the pelvis and vagina, there is at most only a slight degree of prolapse. A generally poor physical condition with a loss of tone and elasticity of muscles is an important predisposing cause of any prolapse, especially if long continued and aided by gravity, and is an important factor in these cases. A fall or strain at this time may cause a sudden stretching of the ligaments, with insufficient elasticity for rebound and replacement, especially if we have a wedge-like cervix with favorable conditions for its rapid elongation, even if not already present by heredity or other causes. You will notice that one of my series occurred in an unmarried woman past the menopause, after a carriage accident. In none of my cases was there a complete tear of the perineum or loss of sphincteric control of the anus. A great majority of them, however, have been constipated, complaining of a lack of expelling force, especially where the abdominal muscles had been overstretched as well.

These patients are usually most uncomfortable, though few of them have severe pain unless they suffer from accompanying hemorrhoids. They complain of a sensation of weight and dragging; many of them have cystitis varying in severity, often due to a pocketing of the bladder, with decomposition of a residual urine; sometimes they are infected with the colon bacillus.

In washing out the bladders of these cases, it is not unusual to catheterize them, and find the argyrol left in the day before. The older patients have usually tried all kinds of pessaries; many of them have had previous repair operations. Their general condition is apt to be poor, and they feel depressed, weak, and discouraged. They often have backache, and sometimes headache and dizziness. Many of them have systolic murmurs, which seem to be due to lack of muscular tone, and may clear up later with rest and tonic treatment. Some of them are fat and bulky; exercise makes them more uncomfortable and they take as little of it as possible. There may be high blood pressure and arteriosclerosis.

Diagnosis. Locally we may find a complete or incomplete extrusion of the uterus, according to the length of the cervix, the degree of laceration

or stretching of the vaginal walls and perineum, and the size of the fundus. If there is much descent, there may be incontinence of urine or leucorrhœal discharge, and we are apt to find erosions or friction sores on the cervix. If the vagina is everted it is usually dry, corrugated, and hard. If partially everted the moist areas may be ulcerated. If there is a large cystocele there is almost certain to be an accompanying cystitis, and it is well to obtain a catheterized specimen of urine. The passage of the catheter may give useful information regarding the presence of stone, pus, or blood, and the direction and length of the urethra. I hear that one of my cases died a year after the plastic operation, from an operation for abscess of the left kidney, and several of them *still* complain of bladder trouble. Fibroids or malignant tumors should be looked for in all cases, both in the fundus, or protruding from the cervix or vulva. In fibroid polypi the question is settled by finding the os externus. Vaginal tumors or a cyst may be present in the incomplete cases, or may exist alone.

Treatment. If aged or tired and depressed, especially if there is any heart lesion, I try to give these patients absolute rest in bed for a few days with a bland nourishing diet, plenty of water, and antiseptic diuretics if necessary. The bowels are thoroughly and regularly moved with cathartics, and if cystitis is present, a daily irrigation of boric acid, or weak permanganate solution if the colon bacillus is present. I then leave about an ounce of a ten per cent. solution of argyrol in the bladder. In all my cases but the first, I used preliminary scopolamine and morphine anesthesia. Either one, one and a half, or two doses, according to the age and blood pressure of the patient, and the judgment of the anesthetist. After the patient has been moved to the operating room she is disturbed, and a little ether may be necessary to begin with, especially if the cervix is to be dilated. I make a routine practice of this, and either use the curette or apply tincture of iodine to the canal, or both. In one patient of sixty-two I found a very tight internal os. Dilatation was followed by a discharge of pus, but as the patient was under the anesthetic I determined to proceed. The result was a moderate infection of the perineum, which rapidly cleared up under treatment, and in no wise affected the result; so I explore every uterine cavity, and always disinfect it with iodine. In cases of low implantation of the anterior vaginal wall one has to be careful not to cut into the bladder; I have seen it as low as the edge of the anterior cervical lip; less care is needed posteriorly. I usually make a circular incision and peel both walls back to the desired length by measurement. Once or twice I have gone through into the peritoneal cavity in a complete case, with no untoward result. I usually tie the lower uterine vessels except in women in the child-bearing period. I then re-

move the denuded cervix, being careful to retain the distal edges with an instrument, otherwise the fundus may disappear from your sight and cause some difficulty and delay in the operation. The vaginal edges are now sewn to the cervical edges with three stitches anteriorly and posteriorly, making a new os. The lateral edges are approximated to each other, being careful not to leave any raw surface, as vaginal adhesions are very liable to form in these cases. I use ordinary chromicized catgut, and leave the middle ends long enough to hold the anterior wall firmly during the operation for cystocele. In my first cases I used the oval denudation, later the triangular, often with some return of the cystocele with both methods. It was in a dissatisfied frame of mind that I went to Chicago and saw Dr. Bertha Van Hoozen do a central flap operation, which she thought was contra-indicated by trachelorrhaphy, but which I have not found to be the case. A straight incision is made in the median line of the cystocele, both flaps are turned back to a pillar of the deep perineal fascia, shown by a white line pointed out by her. The two fascial lines are brought together by interrupted catgut sutures, pushing up the bladder as they are tied, treating it as a hernia. The mucous membrane is now dissected back as far as convenient for easy coaptation, and sewn over the first line of sutures with a continuous catgut stitch. The next consideration is the posterior wall, which often forms a large rectocele. I usually do the Emmet M-shaped denudation, but carry the two angles up as high as possible and attach them to the deep perineal fascia at the sides of the vagina, forming very long arms to the Y when finished. The perineal muscles are brought together and sewn with interrupted stitches of 40-day chromicized catgut. It is essential that these stitches hold for at least two, better three or four, weeks. I seldom remove anything but a few irritating knots during convalescence. Catgut does not cut the skin like silkworm gut. The after-care is easier, is less painful, and does not require removal, a process which is often painful and a source of dread to the patient. If the general condition permits, I remove any hemorrhoids present, but this combination greatly increases the suffering, and it is not my custom to do it unless it is absolutely necessary, especially in the aged.

After-care. I use an ice bag for the first forty-eight hours, with hamamelis or dry gauze on the stitches. Great care is required with regard to the regulation of the bowels and bladder, and irrigation for cleanliness. Where there has been a cystitis I continue my treatment by irrigation and injection into the bladder of a ten per cent. solution of argyrol, with some antiseptic diuretic by mouth. Usually catheterization is necessary. The bladder should be emptied every six or seven hours, oftener if the patient complains of pain. There may be incontinence of urine from the overflow of a full blad-

der, or the patient may squeeze out a few drops from spasm, so in any case use a catheter if there is pain or distention. I have never used a permanent catheter in these cases; it is almost sure to cause an irritation in cystitis in my experience. In two or three of my cases I excised hemorrhoids, and noticed a decided increase of urinary symptoms from this source of nervous irritation and pain. The bowels should be moved in forty-eight hours. I usually give an oil enema just before defecation for the first few days. If there are hemorrhoids, I sometimes mix the oil with lime water, if not, plain or with soapsuds. After peristalsis is well established I find cascara is apt to give painful spasms of the anus, and prefer a milder cathartic. The salines give watery movements and make it harder to keep the perineum clean. Constipation, or a low enema for rapid expulsion, may tear the perineum apart and is to be avoided, especially in the second week when the stitches begin to dissolve. I find that the stronger antiseptics irritate and apparently decrease the vitality of the already depleted tissues, so use nothing stronger than sterile water or boracic acid solution. If the stitches irritate, argyrol gives relief. In some severe cases, a sloughing of parts of the posterior wall or perineum may take place, especially if the stitches have been tied too tightly, or there has been much post-operative edema. If the strong forty-day catgut has been used this has not been serious in my cases, and with care, the after-effect has been quite satisfactory; indeed, one of the best results I have seen was in a case of this kind. After the sloughs came out the tissues closed down into a solid muscular perineum. This patient had a large rectocele the size of a fetal head, and the tissues were thin and much depleted. You must, however, make sure that your fascia holds. I regard the fascial attachment as important as the muscular, there is less strain on it and no elasticity except in the vaginal walls, which give to strain and relax very easily. I formerly kept these patients in bed twenty days. Now I judge according to the case and the age of the patient; at least two weeks is necessary, sometimes three, and if there is any sloughing it may require four. In elderly patients a second operation is often a very serious matter, and no care or pains should be too much for surgeon or nurse. These women are usually veterans of the child-bearing period who have done their duty to state and country, and I feel it a privilege to do my part toward their comfort and restoration to health. They demand our best care in every case; eternal vigilance is their due. Tonics are usually needed during convalescence. The digestion is generally impaired, and careful feeding is sometimes necessary, especially with regard to the gas-producing foods, as starches and sugars. I have seen serious symptoms in one or two of my cases from the pressure of gas on a fatty heart in a stout

and bulky patient. As soon as the patient is up, it is advisable for her to wear some abdominal support, either a belt or front laced corset, as they prefer or the case demands. If not too aged or bulky I find the corset holds up the intestines and decreases the intra-abdominal pressure if worn correctly, having in mind the ptosis which often exists in these cases. In this way it improves the digestion and general health; but if the patient is stout or old, or has never worn corsets, it is a source of irritation to them, and a good fitting belt is better, though not to be worn tightly. In hospital work social service is very valuable, to see that proper hygienic care is given, or followed out. Many of them have a return of cystitis, which could have been prevented or stopped in the early stages. There may be a gradual extension of the infection through the ureters to the kidneys, as in one of my cases. These patients get constipated in spite of all your advice, and by constant straining may bring about more or less return of their original trouble, especially if bloated, or any other cause of increased intra-abdominal pressure exists. When aged their intellect is often not as keen as it used to be, and they need intelligent supervision.

CASE 1. Mrs. L., 69 Widow, American. Operation in May, 1908. This was a case of complete procidentia with erosion of cervix. She was unable to wear a pessary and complained of feeling tired all the time, with numbness of thighs and general lameness. Frequent micturition. Mother of eight children. Widow two years. Menopause twenty years before. After four days' rest in bed with preliminary treatment the operation was performed under ether anesthesia. The internal os was closed, and a gush of pus followed the introduction of the uterine sound. The canal was dilated and disinfected with tincture of iodine. It measured four inches. I removed two inches of the cervix, tying the lower uterine vessels. Oval denudation for large cystocele. Y-shaped colpo-perineorrhaphy. Convalescence interrupted by inflammation of perineal wound, which, however, did not break down and she was discharged in good condition at the end of four weeks. I saw this patient twice, at the end of the first and second years following the operation. She is in good condition, feels well, and perfectly comfortable; she is now 75 years old.

CASE 2. Miss F., 29. Born in N. B. I first saw this patient in April, 1909. She was complaining of attacks of nausea and vomiting, with epigastric pain referred from right side. There was tenderness and rigidity over MacBurney's point. The cervix was long and snout shaped, and protruded from the vulva about half an inch. The uterus was retro-cessed, but easily replacable. She refused operation, so a pessary was fitted and she was referred to another physician for medical treatment. In August of the same year she had an acute attack of appendicitis and was sent to the hospital. After the acute stage had passed the appendix was removed and the uterus suspended with kangaroo tendon by another surgeon. I did not see the patient again for six months, when she returned with the following history: She had felt better till the past

two or three weeks when she developed a cold and cough and now felt as uncomfortable as before the operation. Examination showed an extrusion of the cervix worse than before. The uterus was in the axis of the vagina and there was a separation of the recti muscles. A pessary was worn without much comfort for a year, the patient in the meantime trying to do house work. In June, 1911, the condition getting worse, she consented to further operation. The uterine canal measured four and a half inches. After a thorough dilatation and curettage one and a half inches of the cervix was removed. The abdomen was then opened through the scar, at the same time dissecting it out. No traces of the former suspension were found, and the round, anterior, and broad, ligaments were much relaxed. A Gilliam suspension was done, taking care not to wound the fundus, and the abdomen closed in layers. This girl looked strong and healthy and yet her musculature was very poor; it required much searching to find the two very slender recti muscles. Her convalescence was uninterrupted and she left the hospital in good condition in about three weeks. I hear from her occasionally. She is well and working hard.

CASE 3. Mrs. G., 42, married. Born in Austria. Has had four children and two miscarriages, the last one eighteen months ago. Operated on two years ago for prolapse, with irregular and profuse menstruation. She refused hysterectomy at that time and plastic work was done. Three months later the prolapse recurred and the patient felt no better. I operated on her in September, 1910. Nothing was done to the cervix. An oval denudation was done for the cystocele, followed by a high colpo-perineorrhaphy. Whether flat, or Y-shaped, is not given in the records, and no attachment to the fascia is mentioned. I hear from this patient that she is not well. She has trouble in holding her water and something comes down. She also has some discharge.

CASE 4. Mrs. W., a widow of 60. Operation in September, 1910. Has had five children. The first instrumental, the third craniotomy, no miscarriages. Menopause at 45. History of heavy lifting followed by prolapse two months ago. The cervix was lacerated. Length of canal not given. The cervix was amputated and an oval denudation was done for the cystocele followed by a flap perineorrhaphy. I have heard nothing from this patient.

CASE 5. Miss N., 68. Born in America. Menopause at 50. Operation in March, 1912. First noticed a dragging sensation fifteen months before. Has worn a pessary for the past year. Examination showed a cocoanut-sized tumor, attached to the fundus and freely movable. Cervix long and eroded. Complete procidentia. I did a total hysterectomy, the cervix being removed by request. Convalescence was uninterrupted and the patient was comfortable for about four months when she developed a cough and cold. Suddenly after a fit of coughing the whole vagina came through the outlet in complete eversion. A pessary proved useless and the patient was again operated upon. An oval denudation was made anteriorly and the edges brought together, posteriorly an M-shaped denudation was done, carrying the arms up to the old scar, the middle tongue of vaginal tissue being attached to the deep perineal fascia on both sides. The slender

perineal muscles were dissected out and sewn tightly together with interrupted 40-day catgut, leaving an opening sufficient for drainage and irrigation. She was discharged in three weeks in good condition and is perfectly comfortable since the last operation two and a half years ago.

CASE 6. Mrs. M., 42, married. Born in Prince Edward Island. Sent to the hospital for procidentia. Length of uterine canal not given. High amputation of cervix, oval anterior colporrhaphy, and high Y-shaped perineorrhaphy, attaching the sides to the deep perineal fascia. Discharged in four weeks in good condition. This patient writes that she has some difficulty in holding her water and is suffering from piles.

CASE 7. Mrs. L., 62, married. Born in America. History of one child, no miscarriages. Feels tired, weak and depressed, trace of albumen in the urine; accentuation of second aortic, heart otherwise normal. Examination showed a complete procidentia, with a sharply retroflexed uterus, and long eroded cervix. Operation in May, 1912. Dilatation shows tight contractile internal os with a pus-like discharge; canal four and a quarter inches, disinfected with iodine. A circular incision was made round the cervix, the vaginal walls were dissected up to the peritoneal attachment above the flexion, the lower uterine vessels were tied and the denuded cervix removed. An oval denudation of the cystocele was followed by a long Y-shaped colpo-perineorrhaphy with attachment of fascia. I also removed two hemorrhoids by dissection and continuous suture. This patient had a long and slow convalescence owing to her depressed and nervous condition, but was discharged in good condition at the end of four or five weeks. She had a severe fall the next year, but tells me she is well and perfectly comfortable during the day. She gets up once or twice at night to empty the bladder.

CASE 8. Mrs. S., 53, married. Portuguese. Mother of ten children. Comes for complete procidentia. Operation in June, 1912. Length of uterine canal not given, nor date of menopause. High amputation of cervix, oval anterior colporrhaphy, and long Y-shaped colpo-perineorrhaphy. Discharged in good condition in twenty-two days. This patient's daughter writes to tell me that her mother was perfectly comfortable after the first operation, but that she died two years later following an operation for abscess of the left kidney. Kelly of Baltimore speaks of the great frequency of kidney complications in these cases due to an ascending infection from the cystitis, this, however, is the only one of my cases where I have known it to occur.

CASE 9. Mrs. S., 65, widow. History of one child, no miscarriages. Had a previous plastic operation one year ago. I found a senile uterus with much scar tissue from the previous operation especially on the perineum. A large triangular denudation was made on the anterior wall and sewn with continuous catgut. A long Y-shaped colpo-perineorrhaphy followed, extending the arms of the Y up to the cervical junction, and attaching both sides to the fascia. Discharged in three weeks in good condition. I hear from this patient that she feels well and nothing comes down, but that she has some

trouble in holding her water and is often up several times at night.

CASE 10. Miss N., 32. Born in N. B. Came to see me complaining of backache, bearing-down pain, dysmenorrhoea, and irregular menstruation. Examination showed a prolapse of about two inches of cervix during expulsive efforts; prolapse had been noticed by her for over a year. I operated in February, 1913. The uterine canal measured practically five inches, more than half of which was due to a hypertrophied cervix. I removed two inches of the cervix, after a thorough curettage for endometritis, and made an application of iodine; the uterus was packed anteriorly until the next day, in case of vomiting or straining. Nothing was done to the vaginal walls or perineum. She was discharged in three weeks after a slightly painful menstruation. When I saw this patient a year later she had been practically free from dysmenorrhoea, her periods were regular with less amount, the uterus was anterior, and she had been perfectly comfortable except once after heavy lifting, when there was a sense of weight and fullness for a few days. The ligaments seemed quite able to hold the lighter uterus in good position, though the vaginal walls were somewhat relaxed.

CASE 11. Mrs. G., 40, married. Born in England. Mother of seven children, no miscarriages. History of irregular menstruation for two years. Her general condition was poor, she was stout and bulky, and had a systolic murmur. She was very uncomfortable and often unable to walk. Examination showed a large uterus but no fibroids. Operation in May, 1913. Length of canal not given; much tissue removed by the curette, showing a hyperplastic endometritis. I removed one and a half inches of the cervix, and did an oval denudation of the anterior wall for cystocele, followed by a high Y-shaped colpo-perineorrhaphy. She was discharged three weeks later in good condition. Now she writes to tell me she doesn't feel very well, as she is two or three months pregnant, is constipated, and suffering from incontinence of urine.

CASE 12. Mrs. C., 43, married. Born in N. S. Has had two children, both labors normal. One miscarriage. Comes for irregular and profuse menstruation, prolapse noticed for six months, painful the last two weeks. Has leucorrhoea. Operation in March, 1913. Uterine canal four inches. Considerable tissue removed with curette and canal disinfected with iodine. One and a half inches of cervix removed, nothing done to the anterior wall, Y-shaped colpo-perineorrhaphy. Discharged in three weeks in good condition. I have heard nothing of her since.

CASE 13. Mrs. H., 45, married. Mother of seven children, all normal labors. Two miscarriages, last one six years ago. Operation in March, 1913. Canal four inches. One and a half inches removed, after a curettage and disinfection with iodine. Y-shaped perineorrhaphy. Nothing was done to the anterior vaginal wall, as there was no marked cystocele. She was discharged in twenty-six days in good condition. This patient writes to tell me she is constipated, and the bladder comes down, though she has no difficulty in holding or passing her water.

CASE 14. Mrs. K., 63, widow. Born in N. B. Mother of six children, last one twenty-four years

ago; all normal labors. No miscarriages. Has noticed falling of the womb for two years. Examination showed a complete procidentia with an eroded cervix. The uterine canal measured three and three-quarter inches, fifteen years after the menopause. I removed one and a half inches of eroded cervix, tying off the lower branches of the uterine vessels. I used a triangular shaped denudation on the anterior vaginal wall, and a high Y-shaped perineorrhaphy, attaching the fascia on either side. The patient was discharged after five weeks, according to the records, in fair condition, but she writes to tell me she feels perfectly well, is doing general housework, has no trouble with urination, no discharge and no prolapse. She has, however, a slight lack of sphincteric control of the anus. She is a most happy and appreciative patient, according to her letter.

CASE 15. Mrs. J., 48, married. Born in Sweden. Operation in April, 1913. History of two previous plastic operations nine and one years ago at another hospital. Has had two children, the first an instrumental delivery. Irregular menstruation past two years. Uterine canal measures four inches, cervix small and hard to dilate. Much scar tissue from previous operations. One and a half inches of cervix were removed, the uterus pushed well anterior, and a high Y-shaped colpo-perineorrhaphy done, after dissection of scar tissue. Discharged in twenty-six days, condition recorded as fairly good. I saw this woman a few days ago. The uterus was high in the pelvis and very small; there was no cystocele, but an egg-sized rectocele, starting high above the fascial attachments. A small movable body, apparently a cyst, seems to have prevented the proper healing of the perineal muscles and is still present under the perineal scar. She suffers no discomfort, but is persuaded to try again.

CASE 16. Mrs. J., 60, widow. Menopause seventeen years ago. Has had two children, both normal labors, but torn with the first one, 39 years before. No miscarriages. Has noticed "falling of the womb" for about ten years. Examination shows complete procidentia. General condition poor. Feels weak and tired, and is suffering much pain from hemorrhoids. Has an irregular pulse, and a systolic murmur. After five days' rest in bed with preliminary treatment, the patient was operated upon in April, 1912. The uterine canal measured three and a half inches seventeen years after the menopause, and yet the uterus felt small. I removed the cervix up to the peritoneal attachment, did a triangular anterior colporrhaphy, and a long Y-shaped colpo-perineorrhaphy; I also removed the hemorrhoids at the request of her physician. She was discharged in twenty-four days in good condition, and looked well six weeks later. I hear she continues well, is active, and has perfect comfort. The systolic murmur has disappeared and the pulse has become regular.

CASE 17. Mrs. F., 40, married. American. Menopause three years ago. Has had two children, youngest three, both normal labors. No miscarriages. History of lifting something heavy two and a half years ago; later a bunch appeared at the vulva with pain in the left side and backache. Stout heavy woman with systolic murmur and accentuated second sound of the heart. Operation in April, 1913. Procidentia almost complete. Canal

three and a half inches. Cervix amputated; Y-shaped perineorrhaphy with removal of much scar tissue, also excision of hemorrhoids. Discharged in twenty days in good condition, and I have heard nothing further from her since.

CASE 18. Mrs. C., widow of 71. Born in N. S. Came to the hospital with complete procidentia and eroded cervix. Menopause 31 years ago. She was tired and felt weak, had arteriosclerosis, high blood pressure, and varicose veins of lower limbs. After rest and treatment she was operated upon in April, 1914. Uterine canal measured three and a quarter inches, thirty-one years after the menopause. One and a half to two inches of the cervix were removed, tying the lower branches of the uterine vessels. Straight flap anterior colporrhaphy, high Y-shaped colpo-perineorrhaphy. Discharged in twenty-five days, result not given in the records. She writes to tell me, however, that she feels better than for many years, nothing comes down, she has no trouble with the bladder, but is very constipated.

CASE 19. Mrs. L., 55, widow. Mother of five children, all normal deliveries, though the first was slow and hard. Menopause four years ago. Procidentia past six months. Is now complete. Length of canal not given, but after amputation of the cervix it measured one and three-quarters inches. Operation in April, 1914. Cervix amputated, straight flap operation for cystocele, high Y-shaped colpo-perineorrhaphy. Discharged in twenty-six days in good condition. Patient writes that she is very constipated, and has some trouble in holding her water, but that nothing comes down. She has no discharge, and feels well if she does not overwork.

CASE 20. Mrs. P., 48, married. Born in America. Comes for procidentia, noticed the past year. One child nineteen years old, normal labor. Menstruation irregular for a year. Cervix cystic. Uterine canal three and a half inches. Much tissue removed with curette, showing hyperplastic endometritis. One and a half inches of cervix removed, straight flap operation for cystocele, high Y-shaped colpo-perineorrhaphy. Discharged in twenty-three days in good condition. I hear from this patient that she has felt fine since she recovered from the immediate effects of the operation in April, 1914, and that she has more comfort in standing and walking than for years. She has no trouble with the bladder, no leucorrhea, and is menstruating regularly.

CASE 21. Mrs. L., 58, widow. Born in Russia. Mother of eight children, all normal labors. Two miscarriages, one after last child seventeen years ago. Menopause three years ago. Is short and stout, with a pendulous abdomen. Feels tired all the time, with a dragging sensation of the pelvis, and backache. She also has sciatica. Has noticed prolapse for over a year; bladder trouble on and off for ten years, worse the past three years. Frequent and painful micturition. Examination showed a complete procidentia with eroded cervix. Has been unable to wear a pessary. I did a high amputation of the cervix on this case, tying the lower uterine vessels. A straight flap anterior colporrhaphy was done, and a high Y-shaped colpo-perineorrhaphy, with attachment to the deep fascia. She developed an acute attack of cystitis after the

operation, but quickly recovered under treatment, and was discharged in twenty-three days in good condition. I saw this patient a week or two ago, when she had a slight attack of cystitis, but the mechanical cure was complete. The catheter passed through a straight urethra, there is a good perineum, and no bulging of the vaginal walls.

CASE 22. Mrs. F., 59, married. Born in America. Has had nine children, all normal labors; torn twenty-two years ago with fourth child. Two miscarriages. Comes for "falling of the womb," worse since an attack of bronchitis two years ago. Examination showed complete procidentia, a rectocele the size of a small fetal head, and a moderate sized cystocele. Stout and bulky, with pendulous abdomen. Heart irregular and intermittent; high blood pressure. Complains of feeling weak and tired, with a dragging sensation in the pelvis. Operation in June, 1914. Canal three inches. Many scars holding the uterus, so only about one inch amputated from the cervix, at the same time repairing old lacerations in the vaginal wall. Oval denudation of small cystocele with continuous catgut suture. Large rectocele denuded, puckered, and incorporated into the fascia at the sides of the vagina. High Y-shaped perineorrhaphy. Discharged from the hospital in six and a half weeks. Convalescence interrupted by sloughing of small areas in perineum and posterior vaginal wall, but owing to the 40-day catgut sutures, the muscles and fascia held well, and the end result was good. She also had an acute attack of cystitis after the operation in spite of preliminary treatment. The bladder was capacious and pocketed, argyrol injected one day was often passed in the catheter the following day. I saw this patient about three weeks ago, and she is perfectly comfortable, quite active about her house, and the mechanical result is very good. She has recovered from her sciatica and the cystitis. These patients are a long time in the dorsal position on the operating table, and if there is an old sciatica or lame back, it is quite liable to start up a fresh attack.

CASE 23. Miss C., 50. American. Menopause six years before, after a carriage accident. Has no pain, but a feeling of weight and discomfort in the pelvis. Has noticed prolapse the past six months, with incontinence of urine. No family history of malignancy. Examination showed a complete procidentia. Cervical lips eroded and much thickened, with a small polypus presented at the external os. I did a high amputation of the cervix, opening slightly into the peritoneal cavity. Length of canal three and a half inches, two inches of which were removed. The uterus was pushed anteriorly, and a long posterior colporrhaphy done, extending to the vaginal vault. The overstretched and slender perineal muscles were brought tightly together, and sewn with interrupted 40-day chromicized catgut. Convalescence was uninterrupted, and she was discharged in twenty-two days in good condition. I hear from her occasionally, and she continues well and comfortable.

CASE 24. Mrs. F., 45, married. Born in Ireland. Has had three children, first and last being instrumental deliveries. No miscarriages. Complains of a feeling of weight and dragging in the pelvis, present three years since the birth of her last child, and gradually getting worse. Has dizzy spells. Ex-

amination showed procidentia not quite complete, with a fibrous growth on the posterior cervical lip about the size of a walnut. Canal three and a half inches. Amputation of one inch, after a thorough curettage. Anterior colporrhaphy by a straight flap method, perineorrhaphy by the flap method. Discharged in three weeks in good condition. I have not heard from this patient since she left the hospital two months ago.

CASE 25. Mrs. F., widow. Born in Ireland. Has had two children, first labor instrumental. Menopause fifteen years ago. Sensation of weight and dragging in the pelvis for the past six months. Operation in September, 1914. Complete procidentia past two months. Canal three and a half inches. One inch amputation, anterior colporrhaphy by straight flap method, high Y-shaped colpo-perineorrhaphy. Discharged in twenty-seven days well healed.

Here we have 25 cases to consider which extend over a period of six years. It is noticeable that most of the patients give a history of normal labors, and the one absolute failure was in a case that had been operated on before and the cervix was not amputated either time. I maintain that the removal of the cervical wedge is a very important part of the operation, and I generally find the length of the canal almost double the normal, even in a senile uterus which feels small. We also have to consider the deep perineal fascia which extends from the pubes to the perineal body and ischial spines, with openings for the urethra and vagina. I make use of this fascia in my vaginal work and regard it almost as important as the perineal muscles; where they are atrophied or slender, even more so. I have only used the straight flap method on the anterior wall during the past year. Though it does not stop the cystitis I have not as yet seen any return of the cystocele, and the urethra has been straight in every case to the passage of the catheter. With regard to the bladder symptoms, there has been some return of incontinence in 6 cases, 14 have no further trouble, and 5 have not been heard from. There has been a slight return of cystitis in 2 cases, and 2 have a cystocele which annoys them, though at the time of operation it did not appear necessary to do an anterior colporrhaphy. In one of the cases of incontinence the patient is pregnant, and does not say how she was before she became so. In three cases there is a return of the cystocele after the oval and triangular methods of denudation, and there is some return of the cystocele in two cases where there is no incontinence.

Cystocele of itself then does not necessarily cause incontinence; it is due to lack of sphincteric control. If you pass the dilators into the urethra of these cases you will find them so relaxed that they admit the largest size with slight, if any, resistance, and yet during convalescence they may suffer from retention. After they go home and are more on their feet, the difficulty in holding the water returns, though in

none of the cases has there been complete incontinence afterward. I prefer this method to abdominal fixation or suspension, as in my experience the latter does not cure, unless combined with plastic work. In the aged with a very small fundus, the after-effects are not always comfortable after suspension, due to a dragging on the new anterior ligament, which eventually stretches under intra-abdominal pressure and relaxed outlet, and permits renewed descent. The combined operation is long, and the risk much greater in these patients of lowered vitality, both from sepsis and shock. The few vaginal hysterectomies I have done have not been a cure, unless accompanied by plastic work, even with a vaginal attachment to the round ligaments, and the shock was much greater to the patient. I fail to see any advantage in this, over the high amputation, where eight ligaments have a small piece of fundus to retain, compared to the round and broad ligament attachment to the vaginal walls after hysterectomy, unless there is a question of malignancy or tumor.

Contra-indications. Contra-indications are serious heart and kidney lesions, glycosuria, malignant disease, fibroids, and diseased adnexa. In the patient of child-bearing age, there is no contra-indication if you leave the internal os intact, and allow for involution. I have carefully followed four cases and personally delivered two, where the labor was quick and easy for the first time. One of my patients had borne two previous children with slow hard labors, and the other had given birth to one. Both of them, however, needed extra care afterwards, owing to the tendency to retroversion. I do not tie the lower uterine vessels in these patients, which makes a difference in involution. In the cases of pseudo prolapsus it is not usually necessary to operate on the vaginal walls or perineum if the patient is young, comes to operation in time, and there is no marked retroversion. There must of necessity be a retrocession in these cases, due to the overstretching of the anterior ligaments on account of weight, plus the wedge. If it seems necessary, a retroversion pessary may be worn by the patient for a few months until the tone of the tissue is restored; it will then be found that the ligaments can well take care of the lighter uterus. At first there is involution, followed by a slight broadening of the uterine body. In one of my cases in a young married woman I left a three-inch canal, and three months later the measurement was two and a half inches, so I allow at least half an inch for involution and broadening; more if there is an accompanying endometritis, as the involution will be greater.

Do not in any way decrease the blood supply to the uterus in these cases; they usually need more development. The main thing to guard against is retroversion. When once established, it is often impossible for the patient to wear a pessary to advantage, and some kind of suspension may become necessary. After childbirth the same care is required in all amputated cer-

vices; be on your guard against the increased tendency to retroversion. It has been necessary in two of my cases for the patient to wear a support for the increased weight of the uterus during the first three or four months of pregnancy, until it is well out of the pelvis, on account of the dragging on the already weakened supports of the bladder. In these women there is less question of postoperative shock, but they are often stout, with fat abdominal walls, and a suspension is not always necessary if skilful plastic work is done. The recovery is quicker and there is more subsequent comfort. In some cases a suspension may become a fixation with future trouble for the obstetrician and danger for the patient. Last, but often not least, is the personal dread of some patients to the scar, and they positively refuse anything abdominal on this account.

SOME OBSERVATIONS UPON DIVERTICULUM OF THE BLADDER.*

BY DR. HUGH CABOT, M.D., BOSTON,

Assistant Professor of Genito-Urinary Surgery, Harvard Medical School; Chief of Genito-Urinary Department, Massachusetts General Hospital.

THE subject of diverticulum of the bladder, has, on the whole, attracted less attention, until very recent times, than its importance would justify. Of course, little or nothing was known of these conditions until the routine use of the cystoscope led to their discovery, before such time as they produced recognizable symptoms. There can be no doubt they are a factor of extreme importance because, though they may occasionally exist throughout life without producing important damage to the urinary apparatus, this is the result not at all to be expected, and they are capable of producing an amount of damage which leads to the death of the individual.

Different Types of So-called Diverticula. Some confusion has arisen through failure to separate the different types of pouches or diverticula which are found in the urinary bladder. Thus the small hernial protrusions between the muscular fibres which occur in the subjects of chronic urethral obstruction bear no relation to true diverticula. They are simply the result of weakness of the bladder wall when put under strain; are directly due to the obstruction and lose their importance when that obstruction is removed. The pouch connecting with the vertex of the bladder, due to failure of closure of the urachus, should also be distinguished from the type of diverticula of which I wish to speak here, since it is in and of itself a perfectly definite failure of development, occupies a constant position and is comparatively unimportant in

the surgery of the bladder. The word "diverticulum" should, I think, be confined to those cases of pouches, always of congenital origin, occurring most frequently in certain positions but occasionally seen in almost any portion of the bladder and not due to defective development or lack of closure of any recognized structure. I cannot agree with the view expressed by Chute in a recent paper, that they originate in the little pouches normally seen just above the ureteric orifice, and that they become important only when this pouch is exaggerated as the result of obstructive pressure. My reason for disagreeing lies in the fact that they are so frequently found in individuals in whom obstruction is totally absent, in whom in fact the symptoms of obstruction are due, not to any obstruction, but to the diverticulum. I incline to the view that when found in individuals with urinary obstruction, they are an accidental finding and of no etiological significance. That they are due to some embryonic defect is clear, but I have as yet seen no adequate explanation of their formation beyond the fact that they are associated with peculiarities of the closure of the cloaca, perhaps with a tendency to budding from this structure. It is to be hoped that some of our embryological brethren will produce an adequate explanation.

Congenital Diverticula. These diverticula are covered by the normal coats of the bladder, though the contractility of their muscular fibres is at times certainly defective. The position of election seems to be in the immediate neighborhood of the ureteral openings, and it is to this fact that they owe their greatest potentiality for harm. They are also seen on other portions of the base of the bladder, on the sides and even near the vertex, but those occurring on the upper segment of the bladder can do less damage and are, therefore, less important.

Effects upon the Urinary Apparatus. These effects are largely from two sources: First, those arising from pressure upon the ureter; and second, those arising from the inability of the diverticulum to empty itself completely, and therefore its great liability to infection. The importance of diverticula in the production of hydro-nephrosis has not, I think, been sufficiently emphasized. The frequency with which they occur in relation to the ureter and the tendency of the ureter orifices to lie in the diverticulum or to be drawn into it, at once puts the integrity of the kidney upon that side in jeopardy. The distention of the diverticulum will always put abnormal pressure upon the ureter, and should that structure follow the lower border of the diverticulum (as is not infrequently the case) a valve-like arrangement results which will in time largely or completely obstruct the ureter. I present herewith a specimen of double diverticulum in which this condition has gone on to such an extent as to produce the death of the individual. The history is as follows:

* Read before the American Association of Genito-Urinary Surgeons, in 1912.

CASE 1. March, 1911. H. J. G., 38, wagon maker. Measles and inflammatory rheumatism 20 years ago. Thirteen years ago attack of inflammation of bladder lasting three days, with frequent and painful micturition. Three years ago passed blood following a blow on his side. Eighteen months ago had bloody urine followed by retention after fall on perineum. Habitually constipated. Several attacks amounting to obstipation. Four years ago began to pass large quantities of urine, 14 to 16 pints. Three years ago sugar was found and has been present since. Now passes three to four pints at a time. Comes in for pain in R.L.Q. and in splenic flexure. Fairly developed, thin nervous man. Examination negative except for bladder distended to umbilicus. No sugar found. Bladder drained by catheter, small quantity at a time. Hemorrhagic cystitis resulted. Is most uncomfortable when bladder is distended half way to umbilicus. Remained in hospital one month. Temperature usually normal. Pulse average 96. Towards end of this time patient began to vomit and grow weaker. Bladder was kept empty and urine rarely below 40 ounces a day. He died, with symptoms of uremia.

Pathological Report. Kidneys moderately enlarged and boggy. Renal tissue much thinned. Dilated pelves contain a large amount of rather thin purulent fluid. Ureters much dilated. Right circumference 5cm. Left 6 cm. Bladder wall thickened and trabeculated. In region of opening of right ureter is a diverticulum 4 cm. in diameter, which when distended presses on ureter. In region of left ureter is opening of large diverticulum about 10 cm. in diameter. Opening admits little finger. Opening into left diverticulum is left ureter. Distention of diverticulum occludes left ureter.

Diagnosis. Diverticula of bladder. Cystitis. Pyonephrosis. Broncho-pneumonia, right lung. Obsolete T.B. upper lobe, right lung. Emphysema of lungs. Sero-fibrinous pleuritis, right. Gangrene of tissues of right thorax following saline infusion. Anemia.

In a recent case, a diverticulum of considerable size lay just above the left ureter, which followed its lower margin and opened just at its orifice. In this case distention of the diverticulum produced a valve-like obstruction of the ureter, which was much dilated and thickened. It was very apparent that had this condition been allowed to continue, extensive damage to or destruction of the kidney on that side would have occurred. The history of this case is appended.

CASE 2. May, 1912. M. G., 30, factory. Family and past history negative. For past six months patient has had pain in bladder region with burning micturition. For past two months has occasionally passed blood. Sometimes pain in back. Working or eating heartily seems to make pain worse. O.P.D. record: Bact. report March 26, 1912. Slight growth bacilli. Apr. 6, pig found dead. Too early for diagnosis of T.B. Cystoscopy, J. D. B. Residual, 11 ounces. Bladder irritable. Mucosa red and edematous. Ureters functioning. Jet from right(?) cloudy. Cystoscopy, J. D. B. Residual, 11 ounces. Directly in front of cystoscope to left of mid-line, round opening of congenital diverticulum, with m.m. puckered around opening. Catheter with fine wire inserted into diverticulum. X-ray shows diverticulum.

Physical Examination. Negative. Cystoscopy, Dr. Cabot. O.P.D. Large amount residual. Bladder washes clean without difficulty. Four hundred and fifty c.c. distention. In about position of left ureteral orifice, opening of large diverticulum. Ureter not seen. Cystoscope can be made to enter diverticulum.

Operation. Dr. Cabot. Amph. Ether. Dorsal. Trendelenberg. Bladder washed and distended with boric. Median suprapubic incision. Bladder opened and diverticulum explored with finger. Peritoneum opened and left ureter dissected free and suspended with tape. Peritoneum stripped off bladder. Intestines walled back. With finger in diverticulum this structure was dissected free. No peridiverticular inflammation. Diverticulum opened. Ureteral orifice not seen so ureter opened about three inches from bladder and probe passed through it to bladder. Ureteral orifice located in bladder proper about one-half inch from neck of diverticulum. Diverticulum about size of orange extended downward toward prostate, carrying before it the left ureter. When diverticulum was distended it pressed upon bladder orifice of ureter, tending to close it. Ureter was distinctly hypertrophied and dilated to size of large lead pencil. Diverticulum communicated with bladder by opening which would admit two fingers and appeared to be covered with extensions of all coats of bladder. It was removed at its junction with the bladder and aperture closed with e.g., the mucosa and muscular layer being closed separately. Opening in ureter closed with fine e.g. Sponge count correct. Peritoneal cavity closed. Original opening in bladder closed in two layers. Two large pieces of rubber tissue between peritoneum and bladder. Wound closed to wicks with e.g. and s.w.g. Catheter through urethra.

Excision of diverticulum of bladder. Patient doing well but troubled somewhat by a rather diffuse bronchitis with some pleurisy. Very slight leakage of urine from suprapubic wound due to blocking of catheter. No leakage. Catheter out. Voids O.K. No residual obtained. Wound clean and granulating; strapped. Patient has developed marked phlebitis of whole of left leg. No. T.R. and P. Phlebitis much better. Wound appears solid. Very small granulating area. When dressing was changed today, nearly one ounce of necrotic material came from opening about one-eighth inch in diameter, in site of drainage wick. Opening gently dilated and sinus found to extend for nearly three inches along line of drainage wick. No reaction whatever. Wound again practically dry today.

June, 1913. Came to hospital at request. Scar firm. No urinary symptoms.

April, 1914. Writes in reply to letter that he is perfectly well.

Effects arising from the inability of the diverticulum to empty itself completely and therefore its great liability to infection.

It is not clear whether these diverticula are in their early stages capable of emptying themselves and are, therefore, harmless or whether they are more or less continually the site of residual urine. In the cases that have come under observation, the ability completely to empty themselves has, as a rule, been lost and it is frequently for this reason that they require medical care. Nothing except some other condition

requiring close scrutiny of the bladder would otherwise lead to their discovery. It must be clear that if urine remains in them more or less continually, they are exposed to the same probability of infection as the obstructed bladder. We all of us, I think, believe that urinary retention is one of the commonest, if not the commonest cause of cystitis, and inflammation of a diverticulum must follow substantially the same course. Many of the cases which we have seen have attracted attention because of evidences of urinary infection. Further examination showed that residual urine was present, frequently at an age when obstructing lesions of the prostate do not occur, and the investigation thus started led to their discovery.

The following case is more or less typical of this class:—

CASE 3. October, 1909. L.L., 28, furniture business. Two years ago had an acute urethritis, which was very persistent, involving the prostate and has left him with a cloudy urine. Has been efficiently treated but cloudy urine still remains, though it causes no symptoms.

Seen in August, 1909, with Dr. M. E. P. Fitzgerald. Both vesicles found distended and prostate rather irregular, which was thought to account for his condition. In September seen again and found to have a persistent residual of about five ounces. Operation suggested. An attempt to pass cystoscope in the office was unsuccessful. Condition believed to be one of contracture of the neck of the bladder.

Operation. October 30. Ether. Under an anesthetic, cystoscope passed with some difficulty and shows the opening of a diverticulum on the right lateral wall of the bladder, which will undoubtedly account for cloudy urine. A suprapubic extra-peritoneal cystotomy was done. Orifice of diverticulum found to admit the finger and the sac lay on the right lateral and inferior wall of the bladder. The peritoneum was then stripped off from the right and posterior bladder walls. Peritoneum torn a little at the point of attachment to the urachus. The diverticulum, which had previously been packed with gauze, was readily found at its upper border, and the opening proved to be practically at its highest point. The neck of the diverticulum was divided extraperitoneally and the bladder wall at this point closed with interrupted catgut sutures. The sac thus isolated from the bladder was then freed by blunt dissection and removed. At its lower border it was in contact with the rectum and upper part of the prostate. The ureter, though not seen, was found by passing a ureter catheter to lie upon its lower and outer walls and was not damaged. Bladder wound closed snugly around a medium rubber drainage tube with a Gibson stitch. Abdominal wall closed in layers above and below tube. Protective tissue drain to the right lateral wall of the bladder.

November 2. Drainage has been entirely satisfactory. No leakage around tube until today, when it was removed.

November 7. There has been very little leakage from wound, which is now practically tight. Urine passed freely. There is apparently a little residual urine. Seen in January, 1911. Urine normal. No residual. No symptoms.

THACKERAY'S PHYSICIANS.

By WM. PEARCE COUES, M.D., BOSTON.

NOT the least skilful and clever portrayals of character of the great Victorian novelist pertain to medical men.

Though not the heroes of any of Thackeray's works, physicians have an important place in a few and are mentioned in more than a cursory way in a number of his novels.

Thackeray knew his medicine and medical men of the period well, and all his writings concerning physicians have that inimitable touch, which seems to say, no matter what the subject, "I am master of it." This undoubtedly arises from his attention to detail, and passion for accuracy of description. If he had not known of physicians, he could not have written of them as he did. Of that we may be assured.

In "The Adventures of Philip," a physician is perhaps, next to the hero, the most important character—George Brand Firmin, arch type of the unscrupulous, though clever, society doctor. In his description of this character, Thackeray does not spare the profession, and we know that such types did exist. The portrayal of all the different artifices and subterfuges of this unhappy man is a wonderful example of Thackeray's genius. We have a pen picture of Dr. Firmin as follows:—

"Dr. Firmin's manners were so good, his forehead was so high, his frill so fresh, his hands so white and thin that for some considerable time we ingenuously admired him." We have a picture of him at his club at dinner, choosing a table near a nobleman of vast fortune, though it is draughty and cold. Goodenough, the honest, gruff antithesis of Firmin, cannot conceal his contempt as he watches the other, while he "daintily poured out creaming wine from the ice pail by his side."

At Philip's bar dinner, his father is "called out" by an urgent case, as, Philip groaningly says, always happens. A note is silently presented by the butler, and Dr. Firmin gravely excuses himself—a visit he cannot put off, a friend of high nobility,—he must go.

The elder Firmin meets the fate he well deserves—an execution in his house—he flees to New York, where he draws on his son every now and then, to the latter's chagrin.

In Pendennis we also have Dr. Goodenough, Firmin's antithesis, whose devotion to Pen and skilful care in his illness are graphically described.

Also appears the young surgeon, Huxter, fresh from "Bart's," with dubious hands, writing home of "an interesting case of compound fracture"; the latter is our friend Costigan, with barked shins, the result of too much *spiritus frumenti*, often the case with poor "Cos."

The elder Huxter, the old physician of Clavering, Pen's town, where Fair Oaks is situated, would be much put out at young Huxter's mar-

riage with Pen's former flame, little Fannie Bolton, the portress' daughter, so Lady Rockminster is persuaded to allow him to prescribe for her, and after he has prescribed Spir. ammon. aromat. and Spir. menth. pip. for his august patient, the news is broken to him, and the bitter bolus rendered more palatable by his artful friend Pen, reinforced by Laura Bell, his fiancée.

The immortal Pen's own father was an apothecary and physician, of somewhat humble origin. He started practice in Bath, but was unsuccessful there until Lady Ribstone's drunken chairman cast her through his door, breaking one of Pen's best pink bottles. Pendennis took such good care of her that from that time on his future was assured in Bath and he was a great favorite.
